MITCHELL[1] has reported that under suitable conditions proteins can be spread from a solution to give films the force area curves of which show a sharp transition point in the region of 1·2 dynes/cm., the extrapolated areas of the two distinct portions of the curve being approximately 0·3 and 0·7 × 10^{-7} gm./sq. cm. respectively. The requirements for such a curve seem to be (1) a dilute spreading solution, and (2) a time interval of 1–15 hours between spreading and measurement. Since this is the first case in which a definite transition point has been observed with proteins, we have repeated the measurements using, so far as could be ascertained, the same conditions as Mitchell Dilute solutions of gliadin in 70 per cent aqueous alcohol were used for spreading on $N/100$ sulphuric acid or hydrochloric acid substrates, and the time interval ranged from 3 to 1,065 minutes.

There was no evidence at all of a transition point in any of the curves, and the time interval required for the film to reach equilibrium was only 5 minutes. If the interval was very large (greater than 1–2 hours) the curves indicated that the extrapolated area per molecule was becoming greater. Further investigation showed, however, that this effect was not real and that, in this series of experiments at least, the increase was due, not to a slow spreading of the protein, but to the inevitable accidental contamination of the surface with time. It is extremely doubtful whether a surface can be kept clean for as long a period as 15 hours without taking the most elaborate precautions[1].

The results obtained may be summarized as follows: column *A* gives the time interval between spreading and measurement, *B* the concentration of the spreading solution in grams of dried protein per 100 c.c. of solution and *C* the extrapolated density of the film in gm. × 10^{-7} per sq cm

* $N/100$ HCl, remainder $N/100$ H_2SO_4

For an interval of 5–70 minutes the extrapolated density of the film is fairly constant, the mean value (of experiments 2 to 12) being 1·22 × 10^{-7} gm./sq. cm. with an average deviation of 0·03 × 10^{-7}. This figure (0·82 sq. metres per mgm.) compares favourably with the value of 0·9–1·0 sq. metres per mgm. obtained for various proteins on a substrate the *p*H of which is approximately 1·0 or is at the isoelectric point of the protein[3,4,5], but it is decidedly greater than Mitchell's value, 0·57–0·85 × 10^{-7} gm. per sq. cm. After compression to 18 dynes/cm., the film could be expanded and recompressed to give a curve identical with the first compression. That the decrease in value of column *C* after 70 minutes is not due to a slow spreading was shown by correcting the curves for accidental contamination, obtained from a blank experiment over a similar period of time. Thus experiment 17 on correction gives an extrapolated density of 1·25 × 10^{-7}. The correction applied must necessarily be approximate, and the agreement with the mean value of 1·22 × 10^{-7} is better than was expected; but there seems little doubt that the real cause is contamination and not a slow spreading phenomenon.

Duration of Action of Natural and Synthetic Œstrogens

IN recent communications[1,2], details have been given of the œstrogenic activity of triphenyl ethylene in the mouse, the rabbit, the bitch and the monkey.

A number of derivatives of triphenyl ethylene have since been investigated for their œstrogenic effect and it has been found that triphenyl chlor-ethylene is considerably more potent.

Since a prolonged effect may be a desirable feature in the clinical use of œstrogens, experiments have been made to determine the duration of action of a number of natural and synthetic œstrogenic substances, namely, (1) œstradiol, œstradiol benzoate, œstradiol benzoate butyrate and œstradiol dipropionate; (2) triphenyl ethylene, triphenyl chlor-ethylene; (3) stilbœstrol.

The œstradiol benzoate butyrate and dipropionate were supplied by Dr. Miescher (of Ciba Ltd.) who recently described their prolonged effects in rats[3]. Stilbœstrol[4] was supplied by Dr. Carr, of B.D.H. Ltd.

The substances were tested in mice for their action on the vagina. The changes in the vaginal smear were determined in a quantitative manner by a method previously described[5]. The substances were given either (*a*) by subcutaneous injections in oil in four doses at 12 hourly intervals or (*b*) orally in a single dose in oil. The duration of the effects is shown in Tables 1 and 2.

TABLE 1 DURATION OF ACTION OF ŒSTROGENIC SUBSTANCES GIVEN BY SUBCUTANEOUS INJECTIONS.

Substance	Total dose (μ gm.)	Total duration of effect (approximate) in days	Duration until action halved (days)
Œstradiol benzoate	500	38	27
Œstradiol benzoate butyrate	50	> 120	95
Triphenyl ethylene	10,000	> 110	105
Triphenyl chlor-ethylene	500	> 130	123
Stilbœstrol	500	27	16

TABLE 2 DURATION OF ACTION OF ŒSTROGENIC SUBSTANCES GIVEN ORALLY.

Substance	Dose (μ gm.)	Total duration of effect (approximate) in days	Duration until action halved (days)
Œstradiol	500	23	18
Œstradiol benzoate	500	20	15
Œstradiol dipropionate	500	18	13
Œstradiol benzoate butyrate	500	13	8
Triphenyl chlor-ethylene	500	17	14
Stilbœstrol	500	25	20

The results show that, when massive doses are compared, triphenyl chlor-ethylene given by subcutaneous injection (Table 1) has, weight for weight, a considerably more prolonged action than œstradiol benzoate, which is the œstrogen at present in common clinical use. Œstradiol benzoate butyrate has a more prolonged action than triphenyl chlor-ethylene. The duration of action of stilbœstrol is, in comparison, very short.

When given orally (Table 2), œstradiol has a more prolonged action than any of its compounds tested, Œstradiol and stilbœstrol act for approximately the same time and their period of action is a little longer than that of triphenyl ethylene

Inhibiting Effect of Sodium Chloride on the Oxidation of Ascorbic Acid

IT was recently shown that sodium chloride (0 1 *M*) at *p*H 7 0 has an inhibiting effect on the oxidation of ascorbic acid[1,2]. Kellie and Zilva[2] showed in one experiment that sodium chloride (0 1 *M*) inhibited the catalytic power of copper at *p*H 7 0, but Barron *et al.*[3] did not succeed in demonstrating the same effect at *p*H 6·0. If it is true that sodium chloride has an inhibiting effect on the oxidation, it may be of the greatest domestic importance, for it has always been the practice of man to add salt (primitive people used sea water) to the water used for cooking meat and vegetables.

Experimental. Potatoes, cabbage and ox liver were cooked in glass-distilled water with and without addition of sodium chloride at a concentration of 1 per cent. Potatoes were cooked 45 minutes, cabbage and ox liver 20 minutes. The foodstuffs were added to the water after boiling had started 10 gm. material was cooked with 200 ml. water The foodstuffs were ground up with quartz and in 10 per cent trichloracetic acid and analysed by the method of Emmerie and van Eekelen[4,5] In the table the numbers are the results of double analyses made on different materials. They are given as percentages of the original content of ascorbic acid in the raw substance.

	Cooked in distilled water			Cooked in distilled water with 1 per cent sodium chloride		
	In substance %	In water %	Total %	In substance %	In water %	Total %
Peeled potatoes	93	13 5	106 5	107	17	124
Cabbage	54	20 5	74 5	32 5	56	88 5
Ox liver	46	44	90	38	52	91

Thus we find 16–19 per cent more ascorbic acid left when vegetables are cooked in salt solution than in vegetables cooked in distilled water In agreement with McHenry and Graham[6], we found considerably more ascorbic acid in cooked than in raw potatoes. These authors claimed that ascorbic acid in raw vegetables were partially fixed as esters which are hydrolysed by cooking. Van Eekelen[7] repeated their experiments with another technique using 3 per cent trichloracetic acid for the grinding medium, and found that potatoes, in fact, lost ascorbic acid by cooking, he explained the remarkable results of McHenry and Graham as being due to action of enzymes during the grinding process. In our experiments such an action of enzymes is excluded, since we used strong trichloracetic acid as grinding medium We know of no other observations suggesting that ascorbic acid in vegetables is fixed in the form of esters In our opinion, the phenomenon is easily explained by the fact that it is very difficult to extract ascorbic acid quantitatively from raw vegetables, especially when strong trichloracetic acid is used, and the extraction has to be done quickly in order to avoid destruction of the ascorbic acid

The main purpose with this communication, however, is to point out that vegetables cooked in water containing sodium chloride appear to keep their ascorbic acid better than vegetables cooked in distilled water

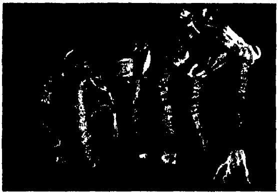
Regeneration of Root Cuttings as Influenced by Plant Hormones

ROOT cuttings (thongs) of sea-kale (*Crambe maritima*) under suitable conditions produce, whichever way up they are inserted in the rooting medium, buds and roots at the morphological apex (proximal end) and base (distal end) respectively (Fig *C*) This phenomenon of polarity has been explained by Went and Thimann in terms of the polar transport of auxin—"polarity can now be expressed quantitatively as a function of the transport of a known substance in the tissues"[1]

Experiments here tended to suggest that the production of buds and roots is possibly dependent on the local concentration of growth substances within the tissues Thongs 7 cm in length were used. The morphological apices were treated for 20 hours with a solution of α-naphthalene acetic acid (0·02 per cent) After 14 days, roots had been produced both apically and basally (Fig *A*). The length of the roots varied from 1 cm. to 5 cm No buds were produced at the apex These observations implied that under normal conditions the presence of a relatively high but quantitative amount of growth substance determines the production of roots. Bud production, on the other hand, may be associated with a relatively low concentration of growth substance. Proof of this would lie in the production of buds basally as well as apically Thus, assuming the polar transport of auxin from all regions to the base, it would be necessary to remove this accumulating auxin and therefore lower the concentration at the base. A possible method of achieving this lay in washing the thongs in running water for 48 hours, but this produced no effect upon the subsequent behaviour of the cuttings. A second method which eventually proved successful was to remove approximately a millimetre of tissue from the base and apex of the thongs every five days for a period of eight weeks. At the end of this time about 25 per cent of the thongs had produced buds at both ends (Fig *B*). Thongs which failed to produce buds basally were either still producing roots in this region or were merely callused The decapitation treatment was continued on the latter material, and after another four weeks most of the thongs had produced buds at the base with no activity at the apex

The quiescence of the apex may possibly be attributed to auxin depletion coupled with carbohydrate exhaustion. Removal of buds from the thongs bearing buds at both ends followed by total immersion of the thongs in a 0 02 per cent solution of α-naphthalene-acetic acid resulted in the production of roots over the whole length Roots and buds formed in anomalous positions showed normal subsequent growth



A Roots at both ends *B* Buds at both ends *C* Normal thong

From these experiments, it is suggested that whatever other substances may be concerned in bud and root production as proposed by Went[2], not only the subsequent growth but also the initial differentiation of meristematic tissue is determined, at least in part, by the local concentration of growth substance

Further experiments will be directed to the possible production of buds by the application of growth substances to tissue whose supply of auxin has been artificially depleted and to the estimation of auxin concentrations, if any, in the different parts of the thong.

Nucleic Acid Metabolism of the Chromosomes in Relation to Gene Reproduction

A relation between the nucleic acid metabolism of the chromosomes and their reproduction is suggested by the localized appearance of thymonucleic acid in the chromosomes preparatory to their division[1]. The study of the nucleic acid metabolism of the salivary chromosomes and of the egg cytoplasm in certain variegated races of *Drosophila melanogaster* has now given evidence of a relation between nucleic acid metabolism and gene reproduction The variegation in these races is due to an abnormality of gene reproduction, consequent upon chromosome rearrangements[2] involving the 'heterochromatic' regions[3] Cytologically, the variegation is correlated with deficiencies in the salivary gland chromosomes for the bands closest to the point of rearrangement, and with a darkening of the immediately adjacent remaining bands which suggests a change in their nucleic acid balance[3].

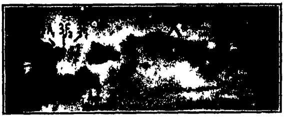

Fig 1

A photograph, taken at 275 mμ showing a normal *X*-chromosome synapsed with one of the chromosomes resulting from a reciprocal translocation between the *X*- and the fourth chromosomes. The labels on the bands are those of Bridges' reference system for the salivary gland chromosomes (*J Hered*, 1938)

Nucleic acid contents of the labelled bands in 10^{-11} mg : $3F_1$ normal 8, translocation 33, $3F_2$ normal 14, translocation 50, $4A_1$ normal 95, translocation 94

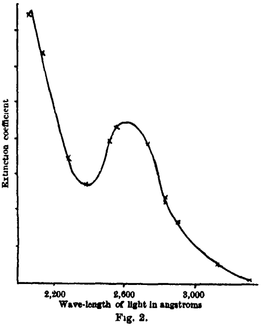

Fig. 2.

Absorption spectrum of the cytoplasm of the *Drosophila* egg.

The nucleic acid content of the bands placed close to the heterochromatic regions in such rearrangements and of their normal homologues has been measured by a photographic method[1]. An increase occurs, which is greatest close to the heterochromatic regions, and less farther away (Fig. 1). Due to the occurrence of deficiencies of various sizes (short ones prevailing in the presence of an extra *Y*-chromosome[4 5,3], longer ones without a *Y*) it has been possible to show that the closer a given band is to the heterochromatic region, the greater the augmentation of its nucleic acid content. It seems not unlikely that the increase in nucleic acid is an intermediate stage between the normal condition and the loss of a band.

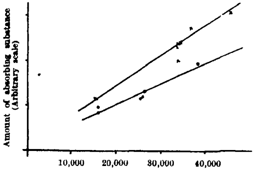

Fig 3

COMPARISON OF THE AMOUNT OF SUBSTANCES ABSORBING ULTRA-VIOLET LIGHT AT 257Mμ IN THE OOCYTES OF AN *XX*- AND AN *XXY*-FEMALE

Crosses represent the values from *XXY*, points those from *XX* ovaries The *XXY* values are consistently higher

The cytoplasm of the egg gives further evidence of a correlation between nucleic acid metabolism and variegation. Its absorption spectrum in the ultraviolet (Fig. 2) measured by a photo-electric method[1] shows the presence of a high concentration of substances containing the pyrimidine ring (hence related to nucleic acid)—a situation similar to the high concentration of nucleotides reported in marine eggs[6] A comparison of the amounts of such substances in the oocytes of *XX*-females and of *XXY*-females (Fig 3) shows an increase due to the presence of the extra *Y*-chromosome. It is known that the presence of an extra *Y*-chromosome in the mother results in the appearance of less variegation in her progeny[7]

These results show effects of the heterochromatic chromosome regions on the nucleic acid content of bands in the same chromosome (in genetical terms, a position effect), on the nucleic acid content of bands in other chromosomes; and on the amount of substances related to nucleic acid in the egg cytoplasm. They suggest that the apparent genetically inert character of these regions is merely the consequence of their specialization in performing a function also performed by all other genes—namely, the synthesis of nucleic acid. The relation of these regions to the variegation, taken together with the local appearance of nucleic acid in the chromosomes, suggests that the synthesis of nucleic acid is closely connected with gene reproduction. The structure-forming properties of thymonucleic acid[8], and its ability to form high-molecular weight polymers[9], as well as the correspondence of its X-ray diffraction pattern with that of the proteins[12], suggest a basis for this function.

These considerations have an especial interest in the case of the other self-reproducing molecules—the viruses and the bacteriophage—all of which have been shown to contain nucleic acid[10,11]. Moreover, in the inactivation of the bacteriophage by ultraviolet light, the curve for the efficiencies of the different wave-lengths does not agree completely with that of the bacteriophage, but does with the nucleic acid absorption spectrum It seems hence that the unique structure conditioning activity and self-reproduction, possibly by successive polymerization and depolymerization, may depend on the nucleic acid portion of the molecule It may be that the property of a protein which allows it to reproduce itself is its ability to synthesize nucleic acid.

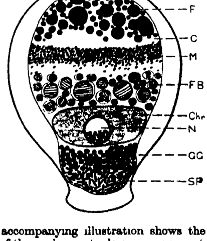
Effect of Ultracentrifuging on *Nebela collaris* Leidy (pro parte)

IN *Nebela collaris*, the cytoplasmic bodies are the glycogen granules, chromidium, mitochondria, one to two contractile vacuoles and sudanophil fat.



The accompanying illustration shows the stratification of the various cytoplasmic components according to their specific gravity after ultracentrifuging. Fat (*F*) and the contractile vacuoles (when present) being lightest, occupy the centripetal position. There follow in turn a clear cytoplasmic area (*C*), the mitochondria (*M*), numerous food-bodies (*FB*) and the chromidial substance (*Chr.*) which contains the nucleus (*N*) near its lower limit. The nuclear contents have collected towards the heavy side of the cell The glycogen granules (*GG*), which have been displaced from the chromidium, lie above the shell plates[1] (*SP*), which, as the heaviest component of the cell, occupy the extreme centrifugal position

It is interesting to note (particularly in this case where a chromidium is present) that no homologue of the Golgi apparatus appears to exist in *N collaris* and that the contractile vacuoles do not blacken with osmic acid even after prolonged periods

Singh[2], working on *Amœba proteus* Y found no homologue of the Golgi apparatus and also that the contractile vacuole did not blacken even after prolonged treatment with osmic acid

Eocene Beds in Waziristan

I SEE that Dr Heron[1] now accepts the fact that Ranikot beds exist in Waziristan The evidence for this is, indeed, overwhelming, as I have pointed out elsewhere[2] He says, however, that Dr Coulson could not state whether the Khirthar overlaps on the Ranikot to the north of Kotkai, so perhaps I may be allowed to quote my own observations

Middle Khirthar (Lutetian) beds to the north, in Waziristan unquestionably overlap on the Ranikot (Paleocene), all intermediate elements, including the Lower Khirthar, being locally absent

Points from Foregoing Letters

DR C V DRYSDALE outlines some novel views on the nature of electrical fields of force in connexion with the flux cutting equations, which he advocates in order to facilitate the teaching of Maxwellian theory He considers that an uncharged body is surrounded by two equal and opposite electric fields, and that a linear current must be surrounded by two opposed electric fields moving translationally past each other, and being thus equivalent to a magnetic field This picture is further elaborated to account for Drude s dispersion theory, Fresnel s drag coefficient and the electro magnetic wave propagation

From observations made in the South Island of New Zealand on radio fadeouts, auroras and magnetic storms which occurred on January 20–22 and 24–26, Prof F W G White, H F Skey and M Geddes conclude that in higher latitudes a radio fadeout may be due to ultra violet radiation emitted during an eruption, or may be due to ionization by the particle radiation causing the auroras They estimate the time interval from the solar eruption to the commencement of the aurora to be about 33 hours

By means of an arrangement which allows the formation and the destruction of a thin liquid film of helium II upon a surface of known area, and allows the measurement of the amount of helium taking place in this process, A K Kikoin and B G Lasarew find the density of the helium film to be 2 to 3 × 10^{-6} cm The viscosity of the film is much higher than that determined by Kapitza for liquid helium II in bulk The heat transfer in the film is high, but may depend upon surface evaporation

Dr C Møller suggests that the part of the nuclear forces which cannot be accounted for by the idea of the heavy electron can be derived from the supplementary assumption of a heavy neutral particle with properties very similar to those of the photon

A G Gaydon and Dr R W B Pearse give the approximate positions of the heads of the strongest bands in the spectrum of RbH, obtained by means of an electric discharge through a mixture of rubidium vapour and hydrogen, and they calculate the approximate values of its molecular constants

A table showing the change with time in the extent of surface films of the protein gliadin is given by G I Jenkins and T W J Taylor The authors calculate the average density during the first 70 minutes to be $1\ 22 \times 10^{-7}$ per gm /sq cm This value decreases with time owing to contamination of the film with surface active impurities The experiments do not confirm Mitchell's sharp transition point in the region of 1 to 2 dynes/cm per cm

Tables giving the duration of the œstrogenic effects of several œstradiol and triphenyl ethylene compounds, administered orally or by subcutaneous injections, are submitted by Dr J M Robson, A Schönberg and H Ahmad Fahim Triphenyl chlor ethylene given subcutaneously has a more prolonged action than œstradiol benzoate

Peeled potatoes and cabbages cooked in water containing 1 per cent of common salt appear to retain their ascorbic acid (vitamin C) better than vegetables cooked without salt, according to experiments by A Høygaard and H Waage Rasmussen Sodium chloride is known to inhibit the oxidation of ascorbic acid

Treatment of root cuttings of sea kale for twenty hours with a solution of α naphthalene acetic acid leads to the formation of roots both apically and basally, while the removal of about 1 mm of tissue from base and apex every five days for eight weeks produces buds at both ends This, Prof R H Stoughton and W Plant point out, indicates that the initial differentiation of meristematic tissue is determined at least in part by the local concentration of growth substances

Differences from the normal values in the nucleic acid content of the salivary gland chromosomes in races of *Drosophila melanogaster* exhibiting variegation have been demonstrated by Prof T Caspersson and Dr J Schultz by optical methods Taken together with other data on viruses and chromosomes, the present results suggest the possibility that nucleic acid synthesis is characteristic of self-reproducing molecules

Lieut Colonel L M Davies states that Middle Khirthar (Lutetian) beds unconformably succeed Ranikot (Paleocene) ones in northern Waziristan.

Research Items

Physical Fitness

IN a paper contributed to the recent British Medical Association meeting, Prof. E. P Cathcart of Glasgow discussed the various factors that go to form the basis of physical fitness (*Brit Med J*, August 6, p. 273). We require to keep a broad and open mind on the problem of how best to achieve fitness—just as there is no one cause of unfitness, so there is no one solution. It will not be achieved merely by satisfaction of the needs of the body, for malnutrition of the spirit is quite as common as malnutrition of the body, and the one reacts upon the other. Discipline is essential for right living, and right living means health. As regards actual factors, muscular activity in the form of physical training is necessary, but must be of the right kind, and posture and carriage are important; but these vary to some extent for the two sexes and for different individuals. The dietary aspect was briefly considered. There is evidence that meat is not essential, and perfect fitness may be acquired on a diet of brown bread, milk, butter, cheese, fresh fruit and salad, provided it is adequate. For heavy work, fat appears to be an important source of energy Sugar and carbohydrates are known to be important sources of energy; but apparently are not immediately available, but have first to be converted into glycogen, so that Krogh *et al.* suggest that in sporting events the athlete should have two days' rest before the contest to secure a complete filling up of the glycogen stores of the body.

South American Head Hunters

THE Jivaro Indians of eastern Ecuador have long been notorious for their custom of preparing shrunken heads as trophies of their enemies killed in battle Much inaccurate information has been recorded concerning them, and their method of preparing the shrunken heads has been shrouded in much unnecessary mystery. The literature relating to their culture, including early Spanish records hitherto somewhat neglected, has been analysed and sifted by Dr W. M. Stirling, and supplemented by ethnographical material obtained in the field in 1930–31 (*Smithsonian Institution Bull*, 117; 1938) The Jivaro, who live scattered over an area of approximately 25,000 sq. miles, are everywhere of similar appearance physically, speak a single language, and their customs, beliefs, and material culture are closely interrelated. They live in small independent groups, for the most part on the head waters of tributary streams of the rivers running through their territory. The groups are constantly at war with one another Their intelligence, fine physique and independent air creates a favourable impression on the visitor. In the study of supernatural beliefs, war customs, and head-hunting, it is demonstrable that their practice, in common with other cultural traits, is not peculiar to them, but was formerly typical over a wide area in the northern Andes. Apparently the blow-gun is a post-Columbian introduction. The high civilization of the Andes at the beginning of the sixteenth century differed from the rather primitive culture of the Jivaros mainly in superficial aspects. A study of the Jivaros to-day and of the ancient tribes of the western Andes, as viewed in historical perspective, seems to indicate that they merely represent different degrees of development from a common cultural background. As regards head trophies, a number of actual examples have been recovered from graves of the ancient culture in the Nasca region These were not shrunken, though there is evidence that the people preparing them had either made shrunken heads themselves or had been in contact with a people who followed that practice. They still skewered or sewed the lips, though this process was not necessary in mummification

Chinook Culture

THE Lower Chinook have been assumed since the last decade of the nineteenth century to be extinct One member of this people furnished Dr. Boas with information in 1890–91 In 1930 Mr Verne F Ray was informed of the survival of two other members, both women of considerable age The material obtained from them by Mr Ray in two expeditions to the Willapa Bay region and the lower Columbia River have been embodied in a series of ethnographic notes (*Univ Washington Pub in Anthrop*, **2**, **2**; 1938) The name Chinook is derived from a Salishan term of the Chehalis dialect, and although the Chinook themselves have no designation for a larger political unit than a village, there is reason to believe that the people of the villages north of the Columbia River did use the term in self-reference, even before the appearance of the whites The Chinook in the early nineteenth century occupied both sides of the river for a distance of fifty miles from the mouth The term Lower Chinook is here used to designate the people of Willapa Bay and the lower river. The population in 1806 was estimated at 1,100. After the smallpox epidemic of 1853 it numbered one hundred. The Chinook lived in villages, each of which was autonomous under a chief The people were divided into upper class and lower class, with a class of intermediates, composed of wealthier members originating from the lower class, and the less energetic and unambitious, or remoter relatives, of the upper class. Class feeling was strong. There was a slave population, which relieved the housewife from the more onerous duties of domestic life. Most of the slaves were obtained by purchase from surrounding peoples The habitat was dominated by the two great connecting bodies of water, Willapa Bay and the Columbia River On these most villages were situated and most travelling was done. The region belongs to the Humid Transition plant life area, and was well supplied with trees, vegetation and animal life. It is probable that few areas of the world could have provided a more desirable habitat than that occupied by the Chinook.

Hydrodictyon in South Africa

ALGOLOGISTS will be glad that Miss Pocock is following her treatise on *Volvox* by studies of other algæ of the South African vleis. She has now given a description of first-hand observations of two species of *Hydrodictyon* (*Trans. Roy. Soc. South Africa*, **24**, Part 3; 1937). Most of the paper is concerned with *H. patenaeforme*, sp. nov., a species formerly referred to *H. reticulatum* or *H. indicum*, but now separated on account of the saucer shape of the nets and the smaller number of component coenocytes; in this connexion, Miss Pocock points out that these might be features of a permanent youth form of *H. reticulatum*, and in this case the South African plant may be only a form of the latter species associated with the absence of asexual reproduction under the local conditions. The photographs and description of the germinating polyhedra are very clear, and it is of interest that the angular thickenings of the wall are absorbed into the membrane during expansion. The whole process of zoospore and net formation was observed to take place rapidly during the first five hours following midnight. The processes of gamete formation and copulation were observed and the author emphasizes the enormous number of gametes produced. The gametes come into contact laterally and fuse whilst still actively motile, forming bi-ciliate zygospores, which also remain active for some time. In *H. africanum* asexual reproduction has not been seen, but reproduction by gametes is similar to that described for *H. patenaeforme*. The separated coenocytes, commonly occurring in the later stages of the alga, appear to have no reproductive function.

Poultry and Poultry Manure

The maintenance of grassland for poultry and the value, storage and utilization of poultry manure is the subject of an interesting bulletin by A. W. Ling and W. R. Muir (Bull. 20, Dept. of Agric. and Hort., Univ. of Bristol). Although it is only within recent years that attention has been paid in Great Britain to grassland in relation to poultry, the improvement that can be brought about on poor pasture by a folding system is now well known, it being possible to convert old down-land into a second-grade cow pasture in twelve months. The method as practised on the drier calcareous soils of the West Country consists of a number of fold units, each containing twenty-five adult birds, the folds being moved daily so that a single unit covers one acre each year. By this system the land is not fouled, the droppings are deposited evenly without loss of soluble constituents and the land is subjected to intense mechanical treatment. As regards the effect of the grass on the poultry, the birds are kept clean and provided with green vegetable matter and protein, but it is essential that the herbage be kept short, by other stock or the mower if necessary, for tufted, rank grass has but little feeding value and is refused by the birds. Frequent liming of land folded to poultry is essential, both to correct soil acidity and to counteract the excessive nitrogenous deposits, ground burnt lime at the rate of 1–2 tons per acre per annum being an average dressing. Moreover, lime in this form will act as a useful disinfectant. Potash as kainit (3 cwt. per acre every fourth year) is also recommended, as intensive poultry penning upsets the balance between phosphate and potash in the soil. The bulletin concludes with practical advice, derived from carefully conducted experiments as to the best utilization of poultry manure.

Pulp Materials

A review of the pulp and paper resources of the Empire (*Bull. Imp. Inst.*, 36, No. 2) directs attention to the general question of raw materials for the paper and allied industries that depend on timber. The outlook stresses the importance of research on new materials. The world consumption of pulp is rapidly growing. It is required not only for paper and various kinds of boards but also for rayon, 'Cellophane', plastics and lacquers. There are, however, indications that the demand for lumber as apart from pulp is slightly diminishing and so affording some relief on forest resources. In Europe, the Scandinavian countries can hold their own by wise afforestation, but cannot materially increase their output of pulp. The U.S.S.R. has vast untapped forests, but her own demands grow as transport improves and Russia is not likely to expand greatly her export. The Canadian forests will be fully taxed to meet the growing requirements of American newsprint. Newfoundland is increasing her export, but on the whole it is clear that the Empire in particular and the world in general urgently requires new pulp resources. Attention is directed to the possibilities: bamboos and other grasses, waste materials such as sisal waste, cotton stalks, rice straw, etc., and various tropical timbers. Any potential material must be available in large quantities, at low cost in a reasonably accessible area.

Advance and Retreat of Glaciers

The complicated relations between climate and the advance and recession of glaciers have recently been discussed by Prof. H. W. Ahlmann and Mr. S. Thorarinsson in an article on the Vatnajökull Glacier (*Geog. Rev.*, July). It is generally accepted that a maritime, in contrast to a continental, climate is favourable to glaciation but, the writers point out, there is a limit to the extent that maritime conditions favour glaciation. That limit is reached when the influx of humid and mild air compensates increasing accumulation by extending the ablation period. Unless a temperature reduction ensues, the glaciers will begin to waste. It is thus obvious that in differing altitudes of mountain regions various glaciers react differently to minor climatological changes: some recede while others advance. In regions with a continental climate a reduction of temperature is probably accompanied by a diminution of precipitation and so by a recession of glaciers, which, however, may leave room for the invasion of glaciers from adjacent regions where precipitation is more active and where the reduction of temperature, by checking ablation, has allowed the glaciers to grow. Another factor of importance is the thickness of the glacier. Deglaciation decreases thickness and, in time, causes rapid marginal recession. The land thus laid bare of ice reacts on the local climate and a change ensues apart from any general climatic change. Conversely the spread of glaciation may in time check the advance of humid winds and so put a stop to the advance and even promote the recession of the ice.

Soil Erosion in East Africa and Australia

The problems of soil erosion in Tanganyika have recently been discussed at length by the director of agriculture (Tanganyika Territory, 1937: Report by H.M. Government to the Council of the League of Nations. H.M. Stationery Office. 4*s*.). While not denying that soil erosion in certain areas is a serious menace, the director points out that the greater part of the territory is not seriously menaced by this threat, since the cultivated soil area is only about one thirtieth of the whole, and he calculates that, taking all causes into account, not more than one tenth is really in danger. Overstocking of grazing land is one source of this danger, but from the native point of view is frequently a necessary evil. Land with persistent vegetation favours ticks, flies and worms which harm livestock. Overstocking promotes aridity which reduces the incidence of parasitic disease, and thus is favoured by native stockowners even at the risk of occasional losses from starvation It is admitted, however, that something might and ought to be done to prevent or at least discourage overstocking. It is noted also that the tsetse-fly, by infesting grazing lands, may cause overstocking of other lands, while in some cases it decreases stock to the extent of promoting the spread of vegetation and so checks soil erosion While various methods of fighting soil erosion are advocated, most stress is laid on educative and legislative measures to govern all cultivation. The subject of soil erosion in general and its cure is also discussed at length, especially in reference to Australia, by Prof Macdonald Holmes in "The Meaning of Soil Erosion" (University of Sydney Publications in Geography No 1 Price 2*s* 6*d*).

Earthquakes and the Surface Structure of the Earth

KATSUTADA SEZAWA has recently published a paper on the amplitudes of Rayleigh waves with discontinuities in their dispersion curves (*Bull* Earthquake Res. Inst, Tokyo Imperial University, 16, Pt. 1; March 1938) In this, he follows up an earlier investigation by himself and Kiyoshi Kanai in which they obtain formulæ exhibiting the relation between the thickness of a surface layer and the amplitudes of dispersive Rayleigh waves, by calculating tables to show that the discontinuity in these dispersion curves does probably exist. The particular case considered is one in which a stratum has beneath it material which is considerably stiffer, and the results therefore apply to waves transmitted along a surface stratum up to a few hundred metres thick In such a case the ratio of wave-length to thickness of the layer is large, and the surface displacement is mainly horizontal when the usual Rayleigh waves are considered. If, however, an earlier phase of the waves the equation of which is obtained by the authors is considered, then a transmission of bodily waves of large vertical displacement should be expected. A similar, though probably more general investigation has been carried out by Stoneley-Rayleigh waves in a heterogeneous medium (*Mon. Not. Roy Astro. Soc.*, Geophys. Supp, 3, No. 6; May 1934) This work is more general in its applicability to the actual conditions existing on the earth. It can be applied to a heterogeneous layer resting on a homogeneous substratum, or to conditions in which the rigidity of the strata vary linearly with distance from the plane of junction.

Petroleum Fuels in Canada

A FURTHER bulletin (No. 789) has now been issued by the Canadian Department of Mines giving statistics of petroleum fuels delivered for consumption in Canada during the year 1936. These statistics are directly comparable with those issued by the same Department for the years 1933, 1934 and 1935 (Nos. 772 and 780). In 1936, 1,213 million Imperial gallons of petroleum products were delivered in Canada for fuel, the total being made up of 555 million gallons of fuel oil, 34 million gallons of kerosene and 624 million gallons of gasolene. In addition, more than 45 thousand short tons of petroleum coke were delivered for the same purpose. More than 89 per cent of fuel oil (as compared with 85 per cent in 1935) was processed in Canadian refineries, the remainder consisting of imported fuel oil. Of this, more than 22 per cent was used for domestic heating, 28 per cent for industrial heating and power, 6 per cent for tractor fuel and 44 per cent for rail and water transportations Kerosene deliveries in 1936 again represented only one thirty-third of the aggregate of all petroleum fuels. In fact, more than 1¼ million gallons less kerosene were delivered than in 1935 67 per cent of the total was used for domestic heating, cooking and lighting, 30 per cent for tractor fuel and 3 per cent for miscellaneous uses The sales of gasolene in 1936 showed an increase of nearly 50½ million Imperial gallons as compared with 1935.

Detection of Hydrogen Cyanide

LEAFLET NO 2 of "Methods for the Detection of Toxic Gases in Industry" (Department of Scientific and Industrial Research, price 5*s*. 6*d* net) deals with hydrogen cyanide. Leaflet No. 1 (price 3*s* 6*d*) dealt with hydrogen sulphide The leaflet No 2 describes a method of detection of hydrogen cyanide which consists in drawing air by means of a hand-pump through a test-paper impregnated with Congo red-silver nitrate or benzidine-copper-acetate, which are capable of detecting concentrations down to 1 part in 100,000 by the production of characteristic stains, specimens of which are included on a card with the leaflet.

Thermal and Photochemical Decomposition of Mercury Dimethyl

RECENT papers from Prof H S Taylor's laboratory at Princeton on exchange reactions involving the simpler saturated hydrocarbons have indicated the importance of the reaction $CH_3 + H_2 \rightarrow CH_4 + H$ as an intermediate process. In order to obtain information regarding the energetics of this reaction the thermal and photochemical decompositions of mercury dimethyl [$Hg(CH_3)_2$] have been studied by J. P. Cunningham and Prof. H S Taylor (*J. Chem. Phys* 6, 359, 1938) The thermal decomposition does not proceed at measurable speed below 290°. Above this temperature $Hg(CH_3)_2$ alone yields a complex mixture of methane, ethane and a carbonaceous deposit, most probably a polymer of CH_2. Addition of hydrogen accelerates the decomposition but now the products consist almost solely of methane and there is no carbonaceous deposit Photochemical decomposition, from 50° to 300°, in the absence of hydrogen, gives practically nothing but ethane below 200° but, in the presence of hydrogen, methane is formed at all temperatures and the higher the temperature the greater the amount of methane formed. The processes involved are the photo-decomposition of the dimethyl to give free methyl radicals [$Hg(CH_3)_2 \rightarrow 2CH_3 + Hg$] which combine to give ethane [$2CH_3 \rightarrow C_2H_6$]. The methane formed is accounted for, in the presence of hydrogen, by the reactions $CH_3 + H_2 \rightarrow CH_4 + H$; and $H + Hg(CH_3)_2 \rightarrow Hg + CH_4 + CH_3$ and, in the absence of hydrogen, by

$$CH_3 + Hg(CH_3)_2 \rightarrow CH_4 + CH_2HgCH_3$$

$$CH_2HgCH_3 \begin{array}{l} \nearrow CH_2 + HgCH_3 \\ \searrow CH_2 + Hg + CH_3 \end{array}$$

$$CH_3 + CH_3 \rightarrow CH_4 + CH_2.$$

The influences of temperature, pressure, and surface on the nature and amounts of products have been noted. The activation energy of the reaction $CH_3 + H_2 \rightarrow CH_4 + H$ is 9 ± 2 kgm.-cal.

Royal Society of Canada

Ottawa Meeting

THE annual meeting of the Royal Society of Canada was held in Ottawa on May 24–27, under the presidency of Prof. A. G. Huntsman of the University of Toronto. Twelve new fellows were elected in the scientific sections, and Dr. Victor Morin of Montreal was elected president for 1938–39.

Dr. Huntsman's presidential address, "The Problem of Life", considered the life-history of the salmon, following which it discussed philosophically the relation between the physical universe and mental processes.

MATHEMATICS, CHEMISTRY AND PHYSICS

The meetings of Section III (Mathematical, Chemical and Physical Sciences) were held under the presidency of Prof. R. H. Clark, who gave the presidential address to the Section on enzyme activators, in which he pointed out evidence suggesting that the action of such chemical materials as hormones, vitamins and bios manifests itself through the activation of some enzyme or bacteria. In all, ninety-nine papers were presented of which about half were given by title only. Among the papers read by the fellows, mention may be made of that by Prof. S. Beatty "On the Cycles of an Algebraic Equation $f(x) = 0$ Relative to Infinity" and "The Stability of Plane Poiseuille Motion" by Prof. J. L. Synge. Prof. R. L. Jeffrey indicated in a paper on "Integration in Abstract Space" the essential difference between the theories of Bochner and Birkoff. A paper of some practical importance in determining the lateral support of towers supported by guy wires was read by Prof. I. W. Campbell. Mr. R. Meldrum Stewart gave an interesting account of the new time signal clock which has been installed at the Dominion Observatory which embodies the two special features of possessing robust electrical contacts and an arrangement for synchronization directly from a precision sidereal clock. A discussion of the results of observations made at Ottawa on the redward shift of spectral lines near the solar limit was presented by Dr. R. E. DeLury.

Among the papers read in the chemical section by Dr. E. W. R. Steacie, mention may be made of one "On the Mercury Photosensitized Decomposition of Ethane" in collaboration with N. W. F. Phillips in which the reaction was traced by separate steps from C_2H_6 to C_2H_2. A series of nine papers were presented by Prof. O. Maass and his associates dealing with viscosity measurements, rates of reaction, specific heat and density measurements of various gases and liquids in the critical temperature and critical pressure region. Prof. W. Lash Miller gave further results of experiments on Wilders' bios. Dr. W. H. Barnes in collaboration with H. B. Yuen presented a translation of an interesting Chinese paper on the Chinese alchemist T'ao, the recluse.

Among the papers dealing with physical topics, Prof. J. S. Foster and Dr. A. Vibert Douglas presented the results of an investigation on the analysis of the Stark effect in helium lines in type *B* stars in which it was shown that the absorption which occurs between the known *d* and *f* lines could not be explained on the basis of laboratory experiments, Doppler effect, relative intensity changes in absorption as compared with emission, or collisional damping. Prof. J. A. Gray gave the analysis of the gamma rays of radium D and radium E in which he showed that Ra E emits no primary γ-rays but 1·5 per cent of the disintegrating atoms emit a secondary γ-ray; which varies in energy from a few thousand volts to a million volts. Prof. J. Satterly gave the results of further investigations of the inclined water jet which definitely disprove Levi-Civita's original theory.

Among the papers communicated by Prof. E. F. Burton special interest was shown in a paper on the measurement of the velocity of sound in liquid helium at ultra-sonic frequency at temperatures ranging from 4·2° to 1·7° K. The velocity varied from 180 to 230 m./sec. over this range. In another paper, by H. E. Johns and J. O. Wilhelm, the refractive index of liquid helium I at 4·2° K. with λ 5461 was found to be 1·0206 ± 0·0012 and for He I at 2·26° K., 1·0269 ± 0·0004. Prof. A. L. Clark and L. Katz described a method of measuring the specific heats of gases by a modified form of the Assmann method. Prof. J. K. Robertson and R. H. Hay gave the results of experiments on the removal of wall deposits from tubes carrying high-frequency discharges and Dr. E. A. Hodgson indicated evidence of the variation in the thickness of the earth's crust from a study of earthquake records. Prof. L. Gilchrist and associates presented papers on applied geophysics, in which the use of drill holes for the central electrode method may be mentioned. Prof. D. A. Keys and H. G. L. Watson gave the results of experiments in the Slocan district of British Columbia using the Broughton-Edge radiometer method and a modification of this arrangement for locating conducting veins of galena.

Prof. W. H. Barnes of McGill, Dr. Ralph E. DeLury of Ottawa and Prof. J. A. McRae of Queen's were elected fellows in Section III.

GEOLOGY

In Section IV, embracing the geological sciences, twenty-three papers were presented. The presidential address by E. S. Moore was on "Some Problems of the Canadian Shield". Prof. Moore, among other things, discussed the Pre-Cambrian granites, the Couchiching problem, and the questions relating to life in the Pre-Cambrian. In another paper he reviewed the problem of the Steep Rock Series, and gave as his conclusion that at Steep Rock Lake, the Steep Rock and the Seine are the same series.

Four interesting papers were given on glaciology. J. T. Wilson described an area in south-western Nova Scotia in which some 2,300 drumlins occur. They can be identified and mapped from air photographs. They are related to slate bedrock and form the good agricultural land of the area. G. W. H. Norman described the last Pleistocene ice front in Chibougamau district, Quebec, and J. T. Wilson the moraines, beaches and large eskers in a neighbouring region of the same province drained by the Harricanaw and Bell Rivers The papers throw considerable new light on the late Pleistocene history of this region R L Rutherford presented some aspects of glaciation in southern and central Alberta

Six palæontological papers were presented Alice E Wilson gave an account of some gastropods from Akpatok Island, Hudson Strait which had been collected by the Cambridge Oxford expedition of 1931 They include twenty species, ten of which are new, and permit certain correlations with the Manitoba Red formation F H McLearn gave an account of the Triassic faunas of the Peace River foothills and R T D Wickenden presented a paper prepared by F H McLearn and himself on some Cretaceous maps of the Canadian interior F M Kindle described the Devonian succession at the eastern end of Gaspé peninsula, and made certain correlations with the Devonian succession as exposed in Matapedia valley A paper by V J Okulitch on some Black River corals was read by title J A Allan described some occurrences of Cambrian rocks in Sunwapta Valley, Jasper Park, Alberta, and L S Russell gave a description of the skull of Hemipsalodon Grandis a giant Oligocene creodont, and showed illustrations of his restoration

L Gilchrist presented a theoretical study of a useful collection of equivalent magnets as an aid to the magnetic exploration of ore bodies J S DeLury discussed his views regarding the significance of association of rock and ore

M Y Williams presented a paper on submarine channels and orogenic movements along the coast of British Columbia Deep channels extend across the continental shelf for a distance of at least 50 miles from the shore line The profile of these valleys suggests a downwarping of the coastal region and verifies the geological conclusions of the existence of a land mass, Cascadia, which is believed to have disappeared beneath the sea during the Miocene

L S Russell presented his views concerning the origin of the sandstone dykes of south eastern Alberta An earlier theory that the material forming the dykes was forced up from below was not accepted Russell believes that the dyke material was introduced from above or from the side during Tertiary times J A Allan described how a relief model of the province of Alberta was prepared and told of its geological applications He also gave a short paper describing a seiche at Yellowknife Bay on Great Slave Lake which occurred while he was there last summer

A paper by N. B Keevil was read describing the application of the helium method of age determination to granites His determinations diminish considerably the commonly accepted figures for the length of geological times

BIOLOGY AND MEDICINE

Prof V E Henderson's presidential address to Section V, entitled "The Search for a Perfect Anæsthetic", consisted of a review of the anæsthetic problem and a critical discussion as to the qualities and shortcomings of some of the more commonly used general anæsthetics, such as ether, chloroform and nitrous oxide. It will be recalled that as a result of work in Prof. Henderson's laboratory in 1930 cyclopropane was introduced and has received world wide approval as a general anæsthetic possessing qualities which the older anæsthetics lack.

Frère Marie Victorin of the University of Montreal discussed certain aspects of the relic flora of Canada, and submitted that earlier views concerning this flora must be modified somewhat more importance being attached to post glacial migrations of various kinds

Mr A E Porsild of the National Museum considered the flora of Little Diomede Island, Bering Strait, pointing out, as a matter of particular phytogeographical interest, that a comparatively large number of circumpolar species common to both sides of Bering Strait do not occur on the island

Dr D C McPherson, University of Toronto, reported that air space development in the root cortex of maize resembles that in certain water plants, in that cortical cells die and their walls collapse leaving the spaces the death of the cells has proved to be due to inadequate oxygen supply

Miss Helen Farley and Prof A H Hutchinson, University of British Columbia submitted an account of ovule development in certain alfalfa hybrids

Prof R B Thomson pointed out that, in the pollen cone of the yew the radial stamen is derived from two stamens of the dorsi ventral type He also discussed the seed cone scale structure of conifers, showing how the *Taxus* or one sided line, and the pine or two sided line have evolved from the araucarian ancestral type

Dr J Ansel Anderson of National Research Laboratories reported that the superiority in malting quality of O A C 21 barley over Wisconsin 38 appears to be varietal in nature and independent of malting method

Dr R Darnley Gibbs, of McGill University, described seasonal changes in the composition of white birch trees on the Island of Montreal Sucrose is the main winter storage form of carbohydrates and doubtless plays an important role in frost resistance

Prof E M Walker showed that the remarkable insect *Grylloblatta* has closer affinities with the *Saltatoria* than other Orthopteroid groups, despite certain primitive features suggestive of the Plecoptera

A contribution from Prof C McLean Fraser, University of British Columbia, considered the distribution of the boreal hydroids, coming in from the polar region as well as those indigenous, to the Pacific area adjacent to Canada and the United States and of the tropical or subtropical species coming in from the south or indigenous to this same area

Dr E Horne Craigie reported an investigation of vascularization of the hypophysis in tailed amphibians, indicating a relation between folding and blood supply only by a superficial plexus

Dr R C Sniffen, Mr H L Collins and Miss H E Williams have been engaged under the direction of Sir Frederick Banting upon researches relating to silicosis Silicosis is caused by the inhalation of rock dust (siliceous dust) which leads to gradual destruction of the delicate tissue of the lungs, and is one of the gravest hazards which north Canadian miners have to face The method of control which shows the greatest promise is one involving the mixing of aluminium dust with the air of the mine Aluminium dust itself is innocuous, and experiments upon animals indicate that it actually neutralizes the poisonous action of the siliceous dust

Three years ago, Dr D A Scott of the Connaught Laboratories made the discovery that certain metals, zinc, cobalt, nickel, etc , are closely associated with the chemistry of insulin, and that in order to obtain crystals of the hormone at least one of these metals must be present in the animal material (beef pancreas) from which the insulin is extracted. In a paper read at this year's meeting of the Society, Drs Scott and Fisher reported on the preparation of nickel insulin crystals; these were found to contain about 0·4 per cent of nickel. Dr Scott's researches have an important practical bearing for it was soon found that zinc, like protamine (a protein material obtained from salmon sperm), prolongs the action of insulin. The improved product, protamine zinc insulin, is now in general use for the treatment of diabetes. This preparation has the great advantage over the older ones in that, owing to its prolonged action, less frequent dosage is required to control the disease—a fact cordially welcomed by the diabetic patient.

An interesting series of experiments on coronary artery thrombosis was described in a paper by Dr C H Best and Dr D Y Solandt. Coronary thrombosis was produced in animals by the injection of a chemical (sodium ricinoleate) into the neighbourhood of one of the main arteries. The electrical changes in the heart during the period of survival and the microscopical appearance of the heart muscle after death were studied.

The researches of Dr P J Moloney and his colleagues in the Connaught Laboratories, as reported in a paper entitled "The Detoxifying Action of Human Bile", reveal the fact that diphtheria toxin is innocuous after being treated with human bile.

Drs W R Campbell and M I Hanna have found that the proportions of the different proteins in the plasma of all healthy persons are approximately the same, nor are they altered in most diseases. In some instances however, they vary in such a way from that seen in health as to be of valuable assistance in recognizing certain diseases.

Dr J K W Willard, in the course of some experiments in British Columbia, accidentally injected some plant hormone into his hand. A tumour developed near the tiny wound. Fortunately it was an innocent growth.

Astronomy's Debt to Photography

THE *Photographic Journal* of April contains the thirty third Traill Taylor Memorial Lecture entitled "Photography in the Exploration of the Universe" which was delivered by the Astronomer Royal Dr H Spencer Jones, on October 19 last when he was presented with the Traill Taylor Memorial Medal of the Royal Photographic Society.

Dr Spencer Jones began by describing the modern photographic method of determining the distances of the nearer stars. From a single plate taken with the Greenwich 26 inch refractor, giving a scale of 30″ = 1 mm, the probable error of the position of a star whose parallax is being determined is about 0·024″ which is equivalent to about 0·0008 mm. The probable error produced by local distortions in the gelatin film does not usually exceed 0·0003 mm, a fact which shows how eminently suitable the photographic plate is for the measurement of minute parallactic displacements given by the changing viewpoint of the earth in its annual journey around the sun. The only visual method of parallax determination comparable in accuracy with photographic methods is that of the heliometer, which in the hands of Bessel one hundred years ago yielded with considerable accuracy one of the first three stellar parallaxes to be successfully determined. It is estimated, however, that the output of results by photographic methods is increased by a factor of 15, since the actual micrometric measures are made at any convenient time subsequent to the taking of the photograph.

At stellar distances equivalent to 400 light years, the trigonometrical method of measuring the distances of the stars breaks down, because the quantities to be measured become increasingly smaller than the probable errors of measurement, microscopic though the probable errors have been reduced to by the most scrupulous attention to every detail. For the determination of stellar distances beyond what is merely the fringe of near-by space, the astronomer makes use of the unique properties of the Cepheid variable stars, which are found not only in the star clusters of our own stellar system (some 120 000 light years in diameter) but are recognizable in the nearer and resolvable extra galactic nebulæ whose unit of distance from us is a million light years. The discovery of the period luminosity relation (which makes the Cepheids criteria of distance), announced by Miss Leavitt in 1912 and extended by Hertzsprung and Shapley was made possible by a series of photographs of the Magellanic Clouds. The yet greater distances of the spiral nebulæ whose stellar structure is beyond resolution into individual stars can be determined by extrapolating the empirical relation found between distance and radial velocity, given by Doppler shifts, of the nearer systems. The photography of the spectra of these faint objects ranging up to 250 million light years away is a veritable *tour de force*. At the focus of the telescope their images are invisible, and the setting of the slit of the spectrograph has to be made in each case by means of a near by star in the field of view whose angular distance from the nucleus of the nebula is obtainable from long exposure direct photographs.

Honours in this triumph of observation have, of course, to be shared between the photographic plate, the giant telescopes employed, the special camera lens (such as the Rayton or the Bracey lens) and the ingenuity and patience of the astronomer. From statistical results of apparent magnitudes, it is deduced that the most distant systems that can be recorded on long exposure direct photographs, on special emulsions of high threshold sensitivity, taken with the 100 in reflector at Mount Wilson, are at a distance of about 500 million light years. Within a sphere whose radius is equal to this limiting distance, it is estimated by Hubble from counts taken from photographs that there are about 100 million stellar systems—veritable universes that are units of the cosmos. A number of slides shown during the lecture and in part reproduced in the article, illustrate the perfection of results given by the photographic plate in recording the Milky Way, gaseous nebulæ, star clouds and individual star clusters, and the remote extra galactic nebulæ.

Coal Carbonization in the Public Service

SO many articles have appeared during recent years on the subject of coal carbonization and the problem is now so interconnected with political issues that one is apt to lose sight of the basic fact which should determine its technical and economic development.

Mr. E. V. Evans, in a lecture delivered at the Royal Society of Arts, on March 2, made the position abundantly clear. Coal and oil resources which are being exploited to-day took millions of years to accumulate. These resources are being used at an immeasurably greater rate than that at which they were formed and for this reason alone none of them should be wasted, no matter in what countries they are situated. It may be that in future years new types of liquid fuel will be produced from different raw materials to meet the ever-increasing demand for that commodity. At present, however, that consideration does not arise and the process of carbonization should be judged finally on its capability or otherwise of husbanding such natural resources of coal and oil as are known to exist to-day.

Carbonizing and electricity generating industries are each capable of contributing substantially towards conservation of natural resources. As a general rule, in the gas industry to-day the thermal energy of coal is distributed into coke, gas and tar in the proportions of 70 : 25 : 5 respectively. Actually 23 heat units of coke are used in the carbonizing process and therefore the thermal efficiency of the process is approximately 77. On the face of it, it would appear that coal has not been saved but the products obtained are more efficient in use, with the result that in the aggregate a greater thermal efficiency is achieved. Moreover, a certain amount of tar and sulphate of ammonia is obtained and a social benefit conferred by the elimination of atmospheric pollution.

The electrical industry has achieved striking results during recent years. In 1917, 3·7 lb. of coal was required to generate one unit of electricity, whereas to-day approximately 1·48 lb. of coal will do the same work. In addition, centralization of power generation has effected great economies. Nevertheless, there is still a tendency among consumers to regard electricity as a very convenient form of fuel and not as a means of transmitting mechanical power. In converting heat energy to mechanical energy approximately two thirds of the original heat energy of the coal is sacrificed. It is definitely uneconomic to use electrical energy for heating purposes. Actual figures can be adduced to show that the capital expended by the electricity companies is two and a half times as great per equivalent ton of raw coal as it is for the gas companies. Each of these industries provides an important public service and the most valuable contribution they can make is to collaborate with each other and be less competitive. There is a great field for expansion of the electrical industry in provision of mechanical power to save human effort, but provision of domestic heat should be the charge of the gas industry.

Special Steels in Marine Engineering

IN response to an invitation to place before the members information concerning the modern special steels with the aim of simplifying their task in availing themselves of the latest metallurgical products, Dr. T. Swinden, director of research to the United Steel Companies, Ltd., delivered before the North East Coast Institution of Engineers and Shipbuilders, on February 25, a paper in which he surveyed the developments of recent years in this sphere. Although his remarks were in many instances more particularly pointed to their applications in hulls, marine boilers, superheaters and engines, his review of the chemical and physical properties of special steels, their amenability to heat treatment, their weldability and their resistance to corrosion and embrittlement were of even wider interest to the engineering profession.

Dealing first with the carbon and low-alloy steels, Dr. Swinden explained the present position as to their special characteristics and then proceeded to enumerate the properties of the more highly alloyed steels which are of increasing importance in engine construction. In addition to comprehensive data of an orthodox character, special attention was given to the subject of fatigue and notch sensitivity, and tables showing results of research on these were included among the many numerical data which the paper contains. From a series of tests on a variety of steels ranging from 20 to 70 tons tensile, it was shown that while the fatigue limit on plain specimens is related approximately to the maximum stress, the notch sensitivity is related roughly to the ductility as measured by elongation. Surface hardening in its various aspects was treated in some detail, the several methods of case carburizing, cyanide hardening, the Shorter process, the Tocco surface hardening process and the nitriding process being discussed and their most favourable applications indicated. Dr. Swinden also dealt with the properties of steels made for use at elevated temperatures, and introduced a discussion on creep and creep strength. As a reliable value on which to base design, he commented on the safe working stress indicated by the stress relaxation method of testing for creep.

Finally, after some notes on stainless steel, Dr. Swinden discussed the possibilities of a stainless-faced composite material which consists of mild steel with a facing of about 20 per cent stainless steel. The method of production admits of the combination of plate material with any variety of stainless steel, resulting in a perfect union between the two metals. This material is extensively used in the United States and, as the author stated, one can readily visualize many purposes in shipbuilding and marine engineering where it could be used with advantage and with definite economy as compared with solid stainless steel.

Scientific Research and Social Well-being

IN his University Research Lecture, 1935–36, delivered at the University of Colorado, O. C. Lester, discussing the development and present status of graduate study and research in the University of Colorado, emphasized the importance of the spirit which animated the Graduate School and the attitude of the faculty to original creative work. The University of Colorado Studies was started chiefly as a medium for the publication of original work by members of the faculty and has been the chief medium of exchange with other universities, and gives important encouragement to creative work by affording a medium for publication.

Another obligation of the university to society is to maintain the supply of trained investigators, and the University's research fellowships and scholarships are designed to assist in discharging this obligation. It is not easy to evaluate the contributions of the faculty to research or other forms of creative scholarship, but the increasing demand for advanced work has led to the appointment of a Council of Research, one of the recommendations of which has led to the inauguration of an annual research lecture, of which Mr. Lester's is the first.

In the remainder of his lecture, Mr. Lester discussed the relation of research, the university and the social order, and particularly the question whether scientific research workers should not modify their traditional attitude of being concerned only with discovery and not with its results to society or with the social consequences of scientific progress in general. The purpose of research is the betterment of human life, and on the whole that has been its effect. Apart from the comforts and conveniences beyond the reach of the rich a hundred years ago which are now possible for the average person, research has led to the eradication or alleviation of many ills of the body. Better understanding of the many factors affecting the health and vigour of both body and mind has led to the development of preventive measures which are becoming more and more effective. Reviewing briefly the organization and support of research, he stressed the supreme importance of the university in fundamental research, both as affording the right opportunity and atmosphere and in maintaining an adequate supply of investigators. The problems of modern civilization are too numerous, too varied, too complex to be solved by a few men, however capable, and the number of research workers, their technical training and the resources at their command required increasing in proportion.

Mr. Lester does not agree that we should be better off if much of our modern science and the appliances growing out of it were scrapped. If scientific advances have disturbed and continue to disturb the economic *status quo*, the remedy lies rather in attaining comparable and co-ordinating progress in the general field of the social sciences. Failure of progress here is indeed largely due to the inability of those who have reached well-founded conclusions to get a hearing, or even to unreasoning opposition to change. We need research on how to use the results of research for the general good, and in such work universities are well qualified to take a leading part. Not merely the general good but also scientific and industrial progress depend on a better social balance. Patchwork emergency methods and methods of political expediency are wholly inadequate for solving complex social problems and must be abandoned for thoughtful planning based upon thorough investigation.

Some French Industrial Laboratories

THE University of Algiers has a small, but well-equipped, industrial testing laboratory under the direction of Prof. L. Vérain, professor of physics in the University. In a lecture entitled "Les Laboratoires industriels", delivered by Prof. Vérain, it is recorded that in 1935, some eight hundred certificates were issued by the Laboratory, the fees received being 56,000 francs.

The Laboratory's interests are many sided: electrical standards, electrotechnics and photometry; a wind tunnel; hydraulics; heat engines and refrigeration plants; the testing of wood, metal, cements, concretes, plasters and road materials; thermal conductivity; acoustic insulation; absolute pressure; viscosity; and X-rays. In connexion with the testing of accelerometers, it is remarked that in Germany a car which cannot decelerate at not less than four metres per sec. per sec. is the subject of penalties if used after warning.

In his lecture, Prof. Vérain remarks that industrial laboratories date from the latter part of last century, when scientific methods were introduced into industry, and he traces their utility in the various stages of development of a process, or in the manufacture of a material or other product. Large works, especially chemical, metallurgical or engineering, commonly have their own laboratories.

In France, the first industrial laboratory was that of the École Nationale des Ponts et Chaussées, the chemical laboratory of which was opened in 1831. The city of Paris set up an engineering laboratory in 1869, and its specifications are still accepted by other organizations. The Laboratoire d'Essais du Conservatoire National des Arts et Métiers, founded in 1900, has five departments, but is not concerned with electrical measurements, for which a laboratory was founded in 1888, under the direction of the late M. Janet. This latter includes a radio laboratory, an engineering testing laboratory, and a co-ordinating office. The French Standards Association (AFNor) has issued some 800–1,000 standards, which may be contrasted with the 5,000 prepared by the corresponding German association.

British Association at Newcastle-on-Tyne in 1838

ON Saturday, August 18, 1838, a meeting of the General Committee of the British Association was held at Newcastle-upon-Tyne preliminary to the formal proceedings of the Association, which began the following Monday and lasted the whole week Eighty members of the committee were present, and owing to the Earl of Burlington being absent on the Continent the chair was taken by Prof Whewell Among other matters it was recommended that collectors should be appointed in places where the meetings of the Association were in future held, and that they should be allowed a percentage of the subscriptions they received

The deaths of Prof. Moll, of Utrecht, and Dr Bowditch, of Boston, U S A, were announced, and it was stated that the Council had elected Prof Dumas and Prof. Liebig foreign members The report touched on the difficulty experienced in finding a qualified person to report on the effects of voltaic and thermal electricity, the question of international copyright, astronomical observations at Madras, and tidal observations, and also the laws regulating the constitution of the General Committee A discussion took place on the last matter, and it was proposed that the committee should consist of (1) the officers of the Association past and present and authors of papers prepared by direction of the Association, (2) members who had contributed a paper to a philosophical society on a subject taken into consideration of the Association; (3) delegates from philosophical societies publishing transactions; (4) delegates from philosophical societies in towns in which the Association met; and (5) foreign and other distinguished individuals whose presence might be deemed advisable

As was its usual custom, the *Athenæum* devoted much space to the doings of the Association, and in referring to the industrial establishments in the district it spoke of the collieries, ironworks, glass, soap, and colour manufactories, the locomotive works of Robert Stephenson and Co, and those of R and W. Hawthorn, where members would be able to see a Harrison patent locomotive with 10 ft driving wheels. Special reference was made to the bridge or viaduct on the Shields Railway, at Ouseburn, which was "of immense magnitude as regards both length and height". At Walker were to be seen the alkali works of Losh, Wilson and Bell, which deserved the attention of the chemist not only on account of their completeness but also because the head of the firm, Mr. William Losh, was "the father of soda-making on the Tyne". There were 250 tons of crystallized soda made per week, besides 400 tons of alkali or soda ash.

According to the *Athenæum*, the general arrangements for the meetings were excellent and nothing had been neglected to ensure a pleasant, a brilliant and a profitable meeting. "The commonalty, however, arguing from these expensive preliminaries, seem to have anticipated a Congress of Princes, or an aggregation of *millionaires*, and in many instances to have increased the rent of their lodgings at least five hundred per cent." Though such attempts were frustrated by the local members, this recurrence should be guarded against in the future, "the limited incomes of scientific men, generally not admitting of these extravagances".

C VANEY Note sur les Crinoïdes de la *Scotia* The collection is a small one, and only a part is here described Species mentioned are. *Isometra vivipara* Mortenson (Burwood Bank); *Ilycrinus australis* Clark (lat 62° 10′ S, 41° 20′ W. in 1,775 fathoms), and a new species, *Ptilocrinus brucei*, described from two specimens (lat. 64° 48′ S, 44° 26′ W. in 2,485 fathoms, and lat 52° 10′ S, 41° 20′ W in 1,775 fathoms)

H D SLACK · The association of non-homologous chromosomes in Corixidæ (Hemiptera-Heteroptera) The examination of twenty species of aquatic bugs of the family Corixidæ has revealed an unusual type of association of chromosomes during spermatogenesis in three species This consists of the fusion of terminal or sub-terminal regions of chromosomes which are not homologous pairs It is first seen at early meiotic prophase and lasts until repulsion forces separate the bivalents at diakinesis, the heterochromatic material uniting the chromosomes being drawn out into fine threads which eventually break. Owing to this association of non-homologous chromosomes, relational coiling of homologues appears to be partially interrupted, but in other respects the course of meiosis remains unaffected.

L C COMRIE and ANN B. ADAM: The female reproductive system and corpora lutea of the False killer whale, *Pseudorca crassidens* Owen. From specimens stranded in the Tay Estuary, 1935, a description is given of the female reproductive system of fœtal, immature and mature animals. Particular reference is made to the corpora lutea, and from their numbers and condition it is tentatively suggested that the age-range of the specimens is 2–20 years

N GALPIN · Factors affecting postnatal growth of brown Leghorn chickens The postnatal growth of brown Leghorn chickens is influenced both by the season of the year at which the eggs are laid, and by the individuality of the parent birds. The seasonal variation shows the same trend as do those of hatching weight and of maternal thyroid weight.

J. P. CHU · Studies on plumage in the male brown Leghorn fowl. A detailed investigation of feathering order, and of changes in feather pattern and structure between hatching and maturity, in the male brown Leghorn fowl. Experimental data indicate that the changes in plumage type are largely dependent on variations in the level of thyroid activity.

D. M. S. WATSON: On *Rhamphodopsis*, a Ptyctodont from the Middle Old Red Sandstone of Scotland: The paper gives a relatively full account of the structure of the whole skeleton of a small Ptyctodont, which shows that the group contains essentially normal Arthrodeiss, peculiar in the reduction of the body armour. Two types of pelvic fin occur, presumably in the two sexes of a single species.

W P Kennedy Seasonal trends of births in Scotland The seasonal incidence of conceptions in Scotland was examined for the period 1880 1935 and a regular seasonal variation was found from year to year the peak of the curve falling in summer the trough in winter On correlating the mean daily conceptions per month with the mean temperature of the month a positive correlation coefficient of 0 671 was found When the period is split into decades the individual correlations do not differ significantly from each other and indeed are remarkably consistent It is considered that there is a real relationship between temperature and the conception rate The higher the mean monthly temperature in Scotland the greater the chances of conception The average range of seasonal difference from the mean of the year is ± 9 per cent

Paris

Academy of Sciences June 20 (*C R* 206 1841–1932)

Henri Deslandres The universal constant of band spectra Attribution of the lines of the band to causes other than the rotation of the molecule

TRADE MARK

CHARLES GRIFFIN & CO., LTD.

Publishers of Scientific and Technical Books since 1820 Included in the Catalogue are works by eminent authors in every field and a publication of great value to scientists which has been issued annually since 1885 is

THE OFFICIAL YEAR BOOK OF THE SCIENTIFIC AND LEARNED SOCIETIES OF GREAT BRITAIN, N IRELAND, AND EIRE

Which book comprises a record from official sources of all activities, the publications, and the elected officers, of Societies, Institutions, and Government Departments engaged in scientific thought and research during Session July 1 of one year to June 30 of the following

Sections cover the following branches of science General — Astronomy — Mathematics — Physics — Chemistry — Photography — Geography — Geology — Mineralogy — Biology — Microscopy — Anthropology — Economic Science — Statistics — Mechanical Science — Architecture — Naval and Military Science — Agriculture — Horticulture — Law — Literature — History — Music — Psychology — Archæology — Medicine A very full index is provided with liberal cross references

Volume on Sale (54th Annual Issue)—1937 Price 10s, net Postage 6d, Abroad 8d (Back issues may be had)

There can be no question that the existence of such an annual volume has promoted the interests of science generally and of the societies with which it deals —Nature

The Significance of Vision for Scientific Progress

LORD RAYLEIGH'S presidential address to the British Association, which is printed in full in a Supplement to this issue of NATURE, is divided into two distinct parts under two titles The first part, dealing with "Vision in Nature and Vision aided by Science", is a masterly general survey of developments in this field, which have taken place largely within the last two or three decades. In simple and direct language—itself a model of what such a survey should be—Lord Rayleigh describes the fundamental aspects of human vision and passes on to review the various ways in which the mechanism of the eye, employed as a means of observation, has been supplemented. The use of lenses, the telescope, the microscope, cathode rays, X-rays, spectroscopy and colour vision, photography and the sensitization of photographic plates, the photo-electric detection of radiation and television are all touched on, the salient features skilfully emphasized and the limitations and prospects of development duly noted. This part of Lord Rayleigh's address will surely bring home the vital fact that the largest part of our knowledge of Nature has been obtained by the sense of sight, and will remind us that progress by this means is not yet exhausted but bids fair, indeed, to go forward to fresh discoveries.

Very important parts of knowledge come, we remember, by the interpretation of images obtained by various optical devices with or without intermediate detection or recording. They are generally found as two-dimensional records of some object-field, although by kinematography and allied methods, and by stereoscopy, the senses of movement and three-dimensional extension can be obtained. But it is probably true that the newer technical methods, for example, the ultra-violet microscope, the iconoscope, and the like have not been exploited to a tithe of their possibilities by those who might use them to the greater advantage. The tendency of biological workers to use the microscope more as an automatic machine, and less as a research instrument, has been regretfully commented upon by those in a position to know the modern way It is true that these methods are available, but they demand a certain training for use —a price which few are apparently willing to pay.

This is true in the extreme sense of the electron microscope, the invention which seems to open up a new world to more 'direct' observation We are, as Lord Rayleigh remarks, very far from the perfecting of such instruments , those who expect them to be sold at a cheap rate in instrument-makers' shops, and to be operated by the laboratory boy, will be disappointed. It will be necessary to recapture the spirit of the early microscopists, for whom the labour of grinding their lenses was not too tedious to be faced, although the difficulties now encountered with high-vacuum technique and the design of electron-optical lenses are quite of another character and not less formidable even to the most sophisticated The results obtained, especially in the microscopy of colloids, are extremely promising, and it seems almost certain that in some fields the method will far surpass anything possible to the optical microscope

"Seeing is believing", no doubt, but it is interesting to speculate how far 'seeing' can go, when the worlds to which we would penetrate are so far out of reach of feeling and the other senses which help to make up our world of experience.

Social and International Relations of Science

THE widespread interest in the social relations to science, which in Great Britain is witnessed, for example, by the founding of the new Nuffield College at Oxford, and of the National Institute of Economics and Social Research, London and elsewhere by the institution last year of the Committee on Science and its Social Relations by the International Council of Scientific Unions and which has since received striking manifestation at the Indianapolis meeting of the American Association for the Advancement of Science has largely been stimulated by the growing anarchy in the international sphere, whether economic or political The threat to freedom of thought inherent in the totalitarian States, the existence of which is indeed only possible through the application of scientific knowledge, provides one of the main stimulants The profound concern engendered everywhere by the increasing scale on which national energies and resources are being devoted to preparations for warfare even to the detriment of standards of living however, provides another source of such interest, both in the ranks of scientific workers themselves and in the population generally

It is, accordingly appropriate that a portion of Lord Rayleigh's presidential address to the British Association should be devoted specifically to the question of science and warfare Although he makes no claim to offer a positive contribution to the subject, at least his remarks should assist to dispel some of those misconceptions which impede that full contact and co operation between scientific workers and their fellow citizens which are essential to effective study or action

A right conception of the position and responsibility of science is a fundamental condition, and Lord Rayleigh's remarks should make it clear beyond question that the discoveries of science which have been utilized in warfare were made in no nefarious quest, and were indeed often laid aside by scientific men as of no practical value

Dismissing, therefore, the idea that scientific men are specially responsible for the application of fundamental discoveries of science to purposes of war, we can face the essential and wider problem of assisting a world anxious to accept the gift of science to make wiser use of the knowledge and powers which science can bring Lord Rayleigh, accordingly, referred to the proposal for the establishment of a Division of the British Association to deal with the social and international relations of science

The whole question has been dealt with very fully in NATURE in recent leading articles The object of the suggested Division, which of course like the various sections of the Association, would be responsible to the Council would be to further the objective study of the social relations of science The types of problems with which it might be called upon to deal would fall under the general headings of the effects of advances in science on the well being of the community, and the effects of social conditions upon advances in science The function of the committee organizing the Division would be to arrange meetings both at the annual meetings of the Association and elsewhere, to appoint speakers and to accept or reject communications It would furnish material for the information of the public co ordinate work dealing with the social relations of science both at home and abroad, and be prepared to act in a consultative capacity and to supply information It would accordingly establish relations with organizations and persons engaged in practical administration, and set up sub committees for executive purposes or for research, inquiry or co ordination

If the Division is to make any significant contribution to the solution of these questions however, the committee will require the widespread and unwavering support of all scientific workers Something more may be called for than the scientific investigation of social and international problems A resolution of the American Association pointedly refers to the inroads being made upon intellectual freedom, and it should be unnecessary to emphasize that freedom of thought and discussion are essential if the new Division is to function effectively Even if the organization of united action in that field falls outside the scope of the Division, it may at least serve to stimulate appropriate action or assist in bringing together professional associations both within and across national frontiers in defence of the most vital condition of the integrity and advancement of science itself

It should be remembered indeed that this is a matter not so much of knowledge itself as of wisdom and values. The advancement of science demands a certain immunity and tolerance to those engaged in scientific discovery and learning, and if the present threat to those liberties is to be resisted, scientific workers in their turn must recognize the normal conditions upon which such tolerance and immunity are accorded. Above all, they must be careful to maintain most scrupulously their intellectual honesty and independence of political pressure

The wise use of science, however, involves especially questions of ethics and values, and is linked up inextricably with the general conditions and standards of the society in which scientific workers are placed. In all such questions the new Division would offer a hope of corporate action in bringing the serious spirit of science to bear in fields and on problems too often the sport of political prejudice, and might well provide another vantage ground from which scientific workers might make their fitting contribution to the solution of the problems of modern society.

Ferns and Fern Allies

Manual of Pteridology
Edited by Dr Fr Verdoorn, in collaboration with A H. G. Alston, I. Andersson-Kotto, L R Atkinson, H Burgeff, H G. du Buy, C Christensen, W Döpp, W M Docters van Leeuwen, H Gams, M. J F. Gregor, M. Hirmer, R E Holttum, R Kräusel, E. L. Nuernbergk, J C. Schoute, J Walton, K. Wetzel, S Williams, H Winkler and W. Zimmermann. Pp. xx + 640 (The Hague Martinus Nijhoff, 1938.) 24 guilders

THE prodigious weight of this volume creates a desire for a light paper suitable for the reproduction of photographs It contains twenty-three chapters, varying much in length, a few in German, most of them well documented and illustrated, written by twenty authors The book is "primarily, but by no means exclusively, designed for the taxonomist who is anxious to improve his methods and broaden his outlook At the same time it offers to the general botanist working on the Pteridophytes the necessary fundamental facts about the group and a survey of the chief results of lines of investigation related to his own".

As Prof. Bower says in the foreword, the ferns and their allies on one hand and the mosses and liverworts on the other hand appear to be separated by a wide gap ; no living plants supply connecting links. He goes on to say that recently acquired knowledge of the oldest land-plants from Silurian and Devonian rocks has furnished some indication of possible transitional forms in the early stages of evolution. It is none the less true that the Bryophyta and Pteridophyta, including both extinct and recent genera, are two sharply contrasted groups. One may go farther and express the opinion that the study of ancient plants as a whole has been disappointing to searchers after missing links.

The first two chapters are by J. C. Schoute of Groningen, who contributes learned essays on morphology and anatomy which make severe demands upon the reader's power of concentration. In a concise historical introduction, Schoute pays a well deserved tribute to the genius of Hofmeister, whose famous paper of 1851 had the effect of a 'flash of lightning' We are reminded that Hofmeister expounded the theory of alternation of generations in three pages, he was master of a lost art! In an academic discussion of morphological conceptions, which contains much that is suggestive and provocative, due prominence is given to extinct types ; the author's views on the stigmarian 'roots' of *Lepidodendron* and *Sigillaria*, and their comparison with the subterranean part of *Isoetes* (quillwort), will be regarded by some botanists as heterodox.

The chapter on anatomy is less satisfactory as an exposition likely to be informative and stimulating to taxonomists who wish to know more about the ancestors of plants which are their special concern References to recent work on fossils are inadequate One would like to have a clearly written essay on, for example, the anatomical structure of the arborescent lycopods and calamites of the forests of the Coal Age as contrasted with the much simpler construction of their living allies. This criticism is equally applicable to other chapters in the volume ; authors, with few exceptions, seem to forget that they are supposed to address themselves to the general botanist. The chapter by S. Williams of Glasgow gives a well balanced and readable account of experimental morphology as an aid to the better understanding of form, development, and evolution. He adopts Prof. Lang's view that the individual development to adult structure is "the manifestation of the properties of the specific substance under certain conditions", and stresses the importance of more intensive research into the physico-chemical problems raised by the work of

Went and others on plant hormones. After quoting the dictum, "experiment cannot reconstruct history", Williams adds, with refreshing optimism "if, however, palæobotanical data and the results of comparative morphology are taken in conjunction with the data derived from experiment, then it may be found that the latter will form a useful contribution to a probable solution of evolutionary problems".

Mary J F. Gregor of Edinburgh gives a survey of work on associations with fungi and other lower plants ; the section on the fossil record is meagre , on the other hand, diseases of both generations in ferns and other Pteridophytes receive thorough treatment Prof Burgeff of Wurzburg contributes a valuable essay on mycorhiza including a particularly full account, with some admirable photographs, of the association of fungal mycelia with the prothalli of *Lycopodium.* This chapter will be of great use to teachers and advanced students A short chapter by W. M. Docters van Leeuwen is devoted to galls caused by mites and insects Cytology, exclusive of the nucleus, is dealt with by Lenette Rogers Atkinson of Amherst It is questionable whether a subject such as cytology can be usefully treated from the restricted point of view necessitated by the scope of this manual This doubt is also suggested after perusal of the chapter entitled "Karyologie" by W. Dopp of Marburg. It is pointed out that the high chromosome numbers and small size of the nuclei in some genera add greatly to the difficulty of investigating nuclear phenomena within the Pteridophyta. It may be, that despite lack of agreement in the nuclei of closely allied plants, additional information on nuclei and chromosomes will throw fresh light on natural affinity. I. Andersson-Kottö's chapter on genetics, which might have been written in less technical language, gives an interesting account of the comparatively small amount of genetical analysis so far undertaken, and directs attention to the promising lines of research presented by fern hybrids and facilitated by the relatively high degree of development of the sexual generation

Growth and tropisms are discussed by H G. du Buy of America and E. L. Nuernbergk of Freiburg : the influence of light on the development of prothalli, including the specific influence of different wave-lengths, is one of many subjects briefly treated. There is an interesting section on the physiological peculiarities of spermatozoids Karl Wetzel of Berlin contributes a chapter on "Chemie und Stoffwechsel" which is a storehouse of facts useful as a source of information for botanists having a knowledge of biochemistry. There are two chapters on the ecology of Pteridophyta : one on extra-tropical members of the group by H Gams of Innsbruck and the other by R. E. Holttum, director of the Singapore Garden Both contain much that is of general interest ; Dr Gams, like many ecologists, forgets that the ordinary botanist is not thoroughly familiar with the superabundant terminology of the subject. Mr Holttum has successfully accomplished the task of digging out references to the ecology of tropical ferns from general papers and has written a very readable and well-illustrated account mainly based on his own researches and observations in Malaya. The geography of Pteridophytes was entrusted to Hubert Winkler of Breslau who gives a good account of a fascinating subject His table of distribution is a little difficult to interpret. Max Hirmer of Munich contributes a well-informed and useful survey of the distribution of fossil Pteridophyta in space and in time ; like some other palæobotanists, he is a believer in continental drift.

Prof. J Walton of Glasgow and A. H G Alston of the British Museum give a concisely written and welcome classification of the Lycopodinæ, both fossil and recent R. Krausel of Frankfort writes with authority on the Psilophytinæ, a group of Silurian and Devonian plants which makes a special appeal to the ingenuity of botanists in search of origins and clues to phylogeny Chapters xviii and xix by Max Hirmer give concise and valuable descriptions of the two living genera of the Psilotinæ, *Psilotum* and *Tmesipteris*, and of the Articulatæ, including the single recent genus *Equisetum* and many extinct genera His account of the latter, though good, makes one wish that he had written an essay which would enable botanists to appreciate the difference between the Palæozoic articulate plants and the solitary living representative of the group.

Carl Christensen of Copenhagen provides a classification of the Filicinæ which is a noteworthy contribution towards a natural system. Fossil ferns and Pteridophyta *Incertæ sedis* are briefly treated by Max Hirmer . there is some overlapping in this as in other chapters between different authors and discrepancies in views that are unavoidable. Prof. W Zimmermann of Tübingen, in the final chapter, which is by no means easy reading, states his views on phylogeny. The Pteridophyta, with their long history and abundant remains preserved in rocks from the Devonian period onwards, would seem to offer an exceptionally rich harvest to students of evolution ; but on the whole they are disappointing. Some of the oldest genera differ too widely from any living types to throw much light on the early stages of evolution , others, from Mesozoic rocks, differ only in minor characters from genera that are still with us. The chapter contains much that is speculative much that is stimulating and yet as one reads it the question recurs Do we estimate too highly the value of these efforts of the imagination as guides to the course of evolution ?

The Manual of Pteridology is well printed and several of the comparatively few illustrations are excellent Its chief value is as a book of reference for teachers and advanced students Considered from the point of view of the editor as stated in the introduction it might have been made more generally useful had authors presented the results of recent research and adumbrated future lines of advance in a more readable less condensed and less technical form With few exceptions the editor s description of the book as a collection of essays is scarcely appropriate

Such criticism as the reviewer has made is not inconsistent with an expression of gratitude to the editor for this the latest of many services generously rendered to botanical science Dr Verdoorn with the help of a company of experts, has produced a volume representing a high standard of achievement which will be heartily welcomed by his co workers and admirers in many countries

ALBERT C SEWARD

The Problem of Time

Time and its Importance in Modern Thought By M F Cleugh Pp x+308 (London Methuen and Co Ltd 1937) 12*s* 6*d* net

THIS stimulating and useful book to which Prof L S Stebbing contributes a short foreword serves a double purpose first it puts before the reader in comprehensive and concise form the problems connected with the conception or experience or whatever we prefer to call it of time and secondly it attempts to contribute something towards their solution The fundamental importance of these problems is now fairly generally realized and it is with some surprise that we learn from Miss Cleugh how recently this realization has come As a consequence books such as this dealing with the general subject are very few in number and a new one therefore calls for some attention

After an introductory statement Miss Cleugh analyses the problem of time into its psychological physical logical and metaphysical elements and each is critically discussed The last named receives by far the greatest amount of attention and the views of Kant Bergson Alexander McTaggart and Dunne are separately dealt with A synthesis follows in which the relevance of time to prediction irreversibility becoming contingency and reality is examined and the author gives her own conclusions (if that is the right word) on the subject The book is completed by a valuable bibliography which as well as the text, bears testimony to the extent of the field surveyed

Miss Cleugh has a happy gift of expression and often makes a subtle point clear by a terse sentence but she tends to discount the effect of this quality by rather involved presentations of extended arguments In the campaign to penetrate the reader s understanding she excels in tactics rather than in strategy There are too many *firstlys secondlys* within *firstlys secondlys* to make the book easy reading and a skeleton plan of each argument would have been helpful It is not the confusion of the thought but that of the presentation which is chiefly open to criticism and the reader who makes the necessary effort can grasp the meaning without ambiguity This is so rare a characteristic of philosophical books that it seems ungrateful to ask for more but since what is lacking could have been so easily supplied it is impossible not to regret its absence

Readers of NATURE will be chiefly interested in the physical aspect of time and this unfortunately is the aspect which is least satisfactorily treated Some important points are well put but Miss Cleugh has certain misconceptions which are so common among philosophical writers on physics (and from which some physicists also are not entirely free) that it is well to point them out She believes that we have a primitive and direct perception of equality of intervals Perhaps so but when she goes on to say that it is on this that the whole of *our measurement* is based (p 40) she is definitely wrong Our measurement is based on the readings of our chosen instruments our direct perception entering only into the observation of *coincidences* not intervals If the clock contradicts our primitive perception we take the word of the clock and indeed it is an essential feature of relativity theory that we may choose a clock which grossly violates our intuitive notion of equality and our measurements will still be perfectly legitimate

Another common misconception is that in physics velocity involves duration before it can be comprehended (p 45) This is not so we speak of velocity *at an instant* and the phrase has meaning We can measure this velocity by an instantaneous observation of a Doppler effect, that is, of a colour ; we do not need to make two observations separated by a duration Again, in her discussion of simultaneity, Miss Cleugh tries to reconcile the plain man to Einstein's apparent absurdities by saying that Einstein means by simultaneity something different from the ordinary notion But this will not do . in so far as the ordinary man has a direct knowledge of simultaneity, Einstein means what he does. The point is that the plain man's direct knowledge of simultaneity is confined to events which he actually experiences, and Einstein gives unambiguous meaning not only to the simultaneity of such events, but also to that of all events occurring at *any* one place Events the simultaneity of which is ambiguous are among those which occur at different places, and of these the plain man must learn to understand that his supposed intuitive knowledge is prejudice.

Finally, Miss Cleugh criticizes the Fitzgerald-Lorentz contraction as an explanation of the Michelson-Morley experiment on the ground that "there is no obvious reason *why* we should assume that our measurements of time are accurate, and that our measurements of space are at fault, since the latter is much easier to measure" (p 53) This criticism arises from a false idea of the experiment, derived from the popular account in terms of the times of travel of the two light beams But this is purely metaphorical : time does not enter explicitly into the experiment at all. What was looked for, and was not observed, was a displacement of interference fringes, and the system of time measurement, conventionally chosen, would merely have determined the magnitude to be assigned to the earth's velocity if the displacement had been observed Space measurement was important because the rods in the apparatus had to be equally long ; but there was no clock in the apparatus, so that whatever motion did to time made no difference.

These points, however, are more relevant to the understanding of physics than to that of time, and their significance in relation to Miss Cleugh's work must not be magnified. Her main concern is with the metaphysical status of time, and our general feeling, after surveying the variety of discussion which she puts before us, is that much labour might have been spared if metaphysicians had taken a hint from science and approached their problems from the point of view of experience. "If I were to attempt to answer in a single sentence the question, 'What is time ?'," writes Miss Cleugh (p 280), "the answer would be, 'The alogical element in the universe' " , her point being that time is inseparably associated with change, and logic can deal only with what does not change. Now this will scarcely do If time is the alogical element in the universe, then the logical elements must be outside time and therefore beyond our knowledge The achievements of science show that that is not so But why drag the universe into the question at all ? Time is concerned with our experience , time is that which immediately removes experiences into the past, where they are inaccessible to change and therefore, on Miss Cleugh's own principle, may be amenable to logic If, then, we begin with experience, we can use our reason freely Problems concerning the future take on a different aspect, for the future is not experience, though it may possibly be anticipated by reason acting on static past experience From this point of view we can make intelligible problems which, from the metaphysical point of view, are involved in contradictions

Nevertheless, it is not wise wholly to ignore the labours of great thinkers, even when we feel that they are wrestling with chimeras. Miss Cleugh has given us a valuable conspectus of efforts, great and small, to reach the heart of the most fundamental of intellectual problems, and men of science as well as philosophers will be thankful for what she has done HERBERT DINGLE.

Greek Reptiles

Die Amphibien und Reptilien Griechenlands. Von Prof. Dr. Franz Werner. (Zoologica · Original-Abhandlungen aus dem Gesamtgebiete der Zoologie, Herausgegeben von R. Hesse, Heft 94) Pp. iv+117+18 plates. (Stuttgart E. Schweizerbart'sche Verlagsbuchhandlung, 1938.) 62 gold marks.

SINCE the old days of Sibthorpe and of the Expédition de la Morée, the study of the Greek fauna and flora has fallen more and more into German hands Erhard, Krüper, Lindermayer and Otto Reiser have told us wellnigh all we know of bird-life in modern Greece, and now, following on the fifty-year-old work of Bedriaga, we have from Dr. Franz Werner an account of the many Greek amphibia and reptiles. The more we learn of the Greek fauna the more thankful we may be. Its varied ecology has many interesting facts and problems for the zoologist. The mountains have a mid-European fauna, the plains are 'Mediterranean', and the Peloponnese is typically 'Greek' ;

the islands differ notably from one another, and the Asiatic or Anatolian fauna begins in Rhodes and Cos and the rest of the Dodecanese. The classical student longs to know more about the several species, their folk-lore, their vernacular names, and all that may elucidate the ancient writers. Now Dr. Werner has given us a good, but it must be confessed a dry account, with many photographs and drawings, of the abundant Greek fauna of frogs and toads, tortoises, lizards and snakes He is a good zoologist , but he very seldom quotes a Greek name, he cares nothing at all for Aristotle, he does not touch on the many ill-identified reptiles mentioned by Nicander in his "Theriaca" Nevertheless his book is of no small interest even to the classical student

There are many poisonous snakes round about the Mediterranean, but in Greece there seem to be only two—*Vipera ammodytes*, widely distributed, and *V. lebetina*, confined to the western Cyclades The Greeks, who are very poor naturalists, are often little aware of how poisonous these vipers are, while they look with superstitious fear on certain harmless toads and snakes and lizards, and show them no mercy Some of the snakes are very large, as indeed Nicander tells us. *Coelopeltis lacertina* (here called by another name) grows two yards long , while among the fierce but harmless species of *Coluber* (or *Zamenis*) the long slender *C najidum*, the σαίττα of the Greeks, common in Attica, and the rarer *C jugularis*, may grow even to three yards long Of 'Greek' tortoises, favourites of the traveller, there are three species, besides two water-tortoises, *Emys* and *Clemmys caspica* , it is the latter which is the common ἁ χελῶνα τοῦ ποταμοῦ. The chameleon, well known to Aristotle, is not found on the mainland of Greece, but only in Chios, Samos, Crete and Asia Minor ; the salamander, on the other hand, common in Greece, is absent from all the islands of the Archipelago The large lizard *Tropidosaurus algira*, commonly said to occur in Greece, is not mentioned by Dr Werner, and there are some other notions current about the fauna which his book will help to correct or dispel.

The price of this small book, 62 gold marks, is quite unconscionable D W T.

Crystal Physics

A Text-Book on Crystal Physics

By Dr W A. Wooster Pp xxii+295. (Cambridge · At the University Press, 1938) 15s net

THIS book is stated to be intended for students at universities, and the reader is forewarned that for its proper understanding a knowledge of the elements of physics, mathematics and crystallography is necessary. A very considerable acquaintance with higher mathematics will certainly be required ; indeed the book has a somewhat forbidding appearance, owing to being overladen with mathematical formulæ and Cartesian tensorial notation. The author obviously recognizes this, for certain chapters and many paragraphs are marked to be omitted at a first reading That the first chapter should be so marked, however, is disconcerting, for it is supposed to explain the tensor notation employed throughout the book.

The author is not very generous, or even fair, to previous investigators. The fallacy is repeated that little was done in crystal physics previous to the discovery by Laue in 1912 ,of the X-ray diffraction by crystal planes, the work which paved the way being entirely ignored. For the most marvellous thing about the X-ray analysis of crystals is the clinching confirmation which it has brought of the conclusions, principles, and possible types of crystal structure, derived from the previous researches, besides its conversion of relative measures to absolute ones Moreover, it is surely incorrect to say that "in particular there was an almost complete absence of researches on the variation of a given physical property in a large number of crystals having chemical or crystallographic similarities". The work of Perrot, Miers, Pope, Barker, von Groth (with his four magnificent volumes of related substances), Becke, Muthmann, Schoenflies, Barlow and Fedorov, and (in all humility) the reviewer, whose thirty years' work on the eighty Tutton salts, and fifteen related simple salts, is now being added to as regards their magnetics by Krishnan, are clear cases of work in the domain of crystal physics which appear to be ignored in the above-quoted statement.

Having said so much in diffident criticism, it must be added that there is a wealth of real value in the book There are, especially, good chapters on thermal conduction and magnetic induction in crystals, on the piezo- and pyro-electric properties of crystals, and on their elastic and dielectric constants The book is admirably printed in larger type than usual, but the illustrations are only line drawings, except two or three figures reproduced from other authors It is appropriately dedicated to the late emeritus professor of mineralogy and master of Pembroke College, Cambridge, Prof. Arthur Hutchinson. A. E. H. T.

Plant Form and Function

By Prof. F. E Fritsch and Prof. E. J. Salisbury. Pp. viii + 668. (London: G. Bell and Sons, Ltd., 1938.) 17*s*. 6*d*. net.

STUDENTS and teachers of botany have in the past made good use of the two text-books by the joint authors: "An Introduction to the Study of Plants" and "An Introduction to the Structure and Reproduction of Plants". In the volume now under review the authors have, in response to many requests, united the subject-matter of both books into a single volume. This has been done successfully by dove-tailing the chapters of the two earlier books very ingeniously, so that the new volume forms a very harmonious whole, and its composite nature can only be ascertained by a careful comparison of the text with that of the component parts. The authors may therefore be congratulated on a clever piece of synthesis The new volume will be appreciated even more than the two earlier text-books, for it gives a more complete as well as a consecutive account of the elementary features of botany and thus facilitates the study of the subject

The authors have taken the opportunity also of bringing the subject matter up to date. This is particularly apparent in the chapter on heredity and evolution, in which the more recent developments of cytology are dealt with and explained In some of the physiological chapters new matter has been added, such as an account of the growth-promoting hormones. New discoveries in connexion with the alternation of generations in the Algæ, heterothallism in the Fungi and recent work on the cytology of the basidium are all dealt with in the new volume. Students will appreciate the fact that to each of the more important sections a selected list of books is given for further reference and also conveniently listed under that heading in the index.

More than a hundred new illustrations have been added. An additional chapter on the British flora as well as the inclusion of additional families in the taxonomic section is a welcome sign that the importance of systematic botany is regaining recognition.

Bacteriology:

a Text-Book of Micro-organisms. By Prof Fred Wilbur Tanner. Third edition. Pp. xiii + 510. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd, 1937.) 17*s* 6*d*. net.

THIS book, though by no means elementary, is designed for the use of those who are studying bacteriology for the first time. The student making use of it should possess some acquaintance with the elements of biology, and the book may then be considered as continuing his biological studies in the domain of micro-organisms, more particularly the bacterial forms, though chapters on the yeasts, moulds and Protozoa are also included. It deals especially with fundamentals, and particular attention is devoted to the structure, nutrition, metabolism and classification of the bacteria, and the action of physical agents upon them; this matter occupies the first half of the book. The second half is devoted to a consideration of the processes involving bacterial action, and chapters deal with the bacteriology of water and milk and canned foods, sewage disposal through bacterial action, and the various industrial fermentations dependent upon bacteria. Finally, the relation of bacteria to diseases, animal and plant, is considered, and the nature of immunity is briefly discussed.

The book gives an excellent survey of all the subjects with which it deals, it is very readable, and the biographical details included of the pioneers of the science increase the interest, it is also well illustrated. The only fault-finding we would register is that the author, in an appended bibliography, in many instances gives the date of old editions of text-books, when much later ones have appeared.

R T Hewlett.

The Chemistry of Antigens and Antibodies

By J. R. Marrack (Medical Research Council, Special Report Series No 230) Pp 194 (London H.M. Stationery Office, 1938) 3*s*. net

IN 1934, the Medical Research Council published, "for the assistance of workers in the field", a report on the chemistry of antigens and antibodies prepared by Prof J. R Marrack. The widespread interest in this report, not only of workers in the subject, but also of many others interested in biochemistry, has led to the decision to revise it in the light of discoveries made during the last four years, and the task has again been entrusted to Prof. Marrack

The admirably wide view of the subject adopted by the author leads to the inclusion of a chapter on physico-chemical considerations, in which topics such as the electronic theory of valency and theories of the structure of proteins are discussed. To those engaged in the field of immunological chemistry, the two chapters on the nature of antigen-antibody reaction will be of particular interest, but to all those concerned in one aspect or another of the chemistry of biological phenomena, this report can be recommended as providing a lucid and comprehensive survey of a field which is, at present, expanding at an astonishing rate

Mea Culpa:

and the Life and Work of Semmelweis. By Louis-Ferdinand Céline. Translated by Robert Allerton Parker Pp. x + 175 (London: George Allen and Unwin, Ltd., 1937.) 5*s* net.

THIS little book consists of two unequal and unconnected portions. In the first, which occupies only 34 pages, the writer, who is a qualified medical man but is best known for his authorship of the unconscionably long and dreary novel entitled "Journey to the End of the Night", makes a frenzied attack on Communism as the result of a recent visit to Soviet Russia. The second part contains a lively and sympathetic account of the great Hungarian medical man, Ignaz Philip Semmelweis, who was a pioneer in the prophylaxis of puerperal fever in the pre-Listerian era, and died insane in 1841 at the age of forty-seven years after failing to convince his contemporaries of the truth of his doctrines.

Polarographic Research on Cancer

By Prof. J. Heyrovský, Charles University, Prague

IT is believed that an account of the scientific foundation and technical details of polarographic research on cancer on which method of serological investigation three letters have recently appeared in NATURE[1,2,3] will be of general interest

A dilute aqueous solution of blood or serum is studied polarographically which means that a direct current is passed through it under increasing voltage in order to record the current voltage curve The cathode consists of mercury dropping slowly (every 3 seconds) from the mouth of a thick walled capillary with a narrow bore (0 05 0 06 mm diameter) the layer of mercury at the bottom of the beaker serves as the anode A few cubic centimetres of the solution are sufficient for carrying out the electrolysis The applied E M F is increased from zero to about 2 volts whilst the current corresponding to the applied E M F is registered photographically The current voltage curves which ensue in this arrangement are independent of the duration of electrolysis and may be repeated any number of times with great reproducibility the current being determined by the voltage and the composition of the solution The theory the practical applications and necessary apparatus for this sort of electrolysis are the work of J Heyrovský and his school * The apparatus automatically recording current voltage curves was called the polarograph[4] the resulting diagrams polarograms and this branch of electrochemistry has been termed polarography[5,6] In the latest model of the recording apparatus the galvanometer shunt potentiometric and photographic drum are all enclosed in one box the micropolarograph suitable for medical and technical applications †

In 1930 a polarographic effect of proteins was described[7] which consisted of a characteristic wave at the voltage of 1 6 on the current voltage curve of a solution of ammonium chloride containing traces of proteins this effect has been shown to be due to the electrolytic evolution of hydrogen catalysed by the presence of the protein at the cathode interphase

Since then the protein effect has been investigated in the Physico Chemical Institute of the Charles University by R Brdicka[8] who introduced a more specific polarographic reaction for the proteins by adding to the 0 1 N solutions of ammonium chloride and ammonia a solution of a cobaltous or cobaltic salt of about 0 001 N He has shown that proteins containing sulphur cause in such solutions a new wave at a smaller voltage (1 4) and ascribed this effect to the sulphydryl and di sulphidic groups of the protein This conclusion is supported by the fact that simple thio acids like thio glycolic acid cysteine or cysteyl glycine or their di sulphidic forms produce a similar catalytic polarographic effect[9] but only in the presence of salts of divalent cobalt whereas higher polypeptides and proteins give the effect also in the presence of salts of trivalent cobalt With this very sensitive and reproducible reaction Brdička was able to work out a micro analytical estimation of cystine in one short piece of hair follow the kinetics of hydrolysis of proteins and determine the proteolytic activity of pepsin[10] In 1936 he became acquainted with the work of A Purr and M Russel who found that carcinomatic blood shows in certain biological reactions less activity than normal blood F Waldschmidt Leitz and his collaborators[11] attempted to use this reaction for cancer diagnosis and expressed the opinion that the lack of activity of the carcinomatic serum is due to decreased activity of the sulphydryl groups in the proteins of blood serum

Brdička now tried his polarographic reaction, which gives the activity of the sulphydryl or di sulphidic groups in the blood serum to compare them in normal and carcinomatic serum On direct comparison of the native sera but little difference is shown However if denatured sera are compared a distinctly lower polarographic protein effect in the pathologic sera is found The denaturation may be effected by adding alkali to the serum and allowing it to stand at room temperature Another way which also leads to considerable differences between normal and carcinomatic sera is to add 0 2 c c of the serum to 5 c c of 0 05 N hydrochloric acid containing 5 mgm of pepsin and to keep the mixture at 40° C After half an hour 0 2 c c of the mixture is withdrawn added to the cobaltous Brdička solution (0·1 N ammonium chloride 0 1 N ammonia 0 001 N cobaltous chloride) and the polarographic curve of this solution is registered (between 0·8 and 1 8 v) In this manner the polarogram reproduced

---

*For bibliography see Collection of Czechoslovak Chemical Communications 10 1938, p 153-173 In the same journal most of the work appeared as Polarographic Studies

†The sole polarograph maker with whom the inventor collaborates is Dr V Nejedlý Prague XIX, Kladenská 76 in America these genuine polarographs may be obtained from E H Sargent & Company 155 East Superior Street Chicago

as Fig. 1 was obtained. The denaturation or the peptic action liberates the disulphidic groups through a re-arrangement or cleavage of the micellar structure of the protein molecules, thus indicating that the carcinomatic serum contains fewer sulphur groups than the normal one This conclusion was verified by the estimation of cystine in the hydrolysates of the normal and pathologic sera examined, when Brdička obtained the same differences—both polarographically and colorimetrically—in the content of cystine as were found by his protein test[3]

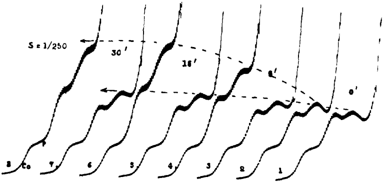

Fig 1

Liberation of the polarographically active groups of proteins by peptic cleavage Curves 1, 3, 5, 7, with carcinomatic serum, Curves 2, 4, 6, 8 with normal serum, in cobaltous Brdička's solution. Sensitivity 1/250, voltage 0 8–1 8 Curve 8. Co denotes the cobaltous 'wave', P the protein 'wave' The curves were recorded after 5, 15 and 30 min of the reaction

Another significant reaction has been worked out by K. Mayer in collaboration with Brdička in the Physico-Chemical Institute of the Charles University, involving deproteination of the serum[13] For this purpose 0 5 c c of serum is added to 1 0 c c of 0 1 *N* potassium hydroxide, and after standing one hour the proteins are precipitated by the addition of 1 5 c c 20 per cent sulphosalicylic acid , 0 5 c c. of the filtrate is added to the cobaltic 'Brdička solution' (0 1 *N* ammonium chloride, 0 1 *N* ammonia, 0 001 *N* cobaltammine, $Co(NH_3)_6Cl_3$) In this manner the liquor is freed from proteins ; however, their decomposition products—the albumoses—remain partially in solution. Investigations have shown that carcinomatic sera have a larger content of these products soluble in sulphosalicylic acid than normal sera. Consequently an abnormally high 'wave' obtained after deproteination (Fig. 2) indicates a pathological case, just as does the abnormally low 'wave' obtained after peptic cleavage (Fig. 3). The degradation of the protein molecules, which thus is shown to take place in the carcinomatic serum, may be effected artificially by treating a normal serum with alkali or pepsin, by which the products partly soluble in sulphosalicylic acid are split off and cause then the latter polarographic pathological effect.

The pathological state indicated by the abnormal height of Brdička's protein 'wave' has been ascertained to be due to carcinoma or sarcoma—if acute cases of inflammation or fever are eliminated The serum in the latter pathological state gives with either reaction an abnormal, that is, a 'positive' effect Investigations are now being directed towards distinguishing whether the decomposition products of the serum proteins due to cancer are different from those due to other diseases (inflammation, fever) so as to make the polarographic reaction in this respect more specific

The first systematic research using the polarographic diagnosis of cancer was carried out by Brdička in collaboration with Dr F N. Novák, director of the Radio-Therapeutic Institute, Bulovka, Prague . from 187 cases, the polarographic diagnosis agreed in 102 out of 107 histologically ascertained carcinomatic cases, 11 of the 13 sarcoma cases, whilst one of the 38 normal sera showed a positive polarographic reaction ; of the 29 non-carcinomatic diseases, 14 were polarographically positive and 15 negative.

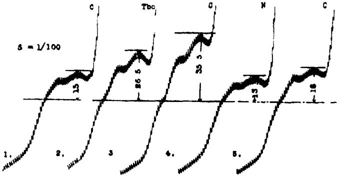

Fig. 2.

Pathological sera compared with normal serum after deproteination. (1) Ca portionis vaginalis (2) Fungus genus sinitri (Tbc) (3) Ca ventriculi. (4) Normal serum. (5) Ca ventriculi.

A similar agreement was found in the Finsen Institute and Radium Station, Copenhagen[3], where amongst the positive reactions some cases of hepatic disorder were ascertained. The polarographic cancer diagnosis is being successfully applied also in the Institute of Organic Chemistry (director Prof E Waldschmidt Leitz) and in the Gynæcological Clinic (director Prof H Knaus) of the German University Prague and at several hospitals in Czechoslovakia and in Germany

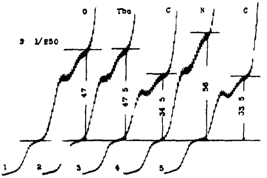

Fig 3

PATHOLOGICAL SERA COMPARED WITH NORMAL SERUM AFTER TREATMENT WITH PEPSIN CURVES 1–5 REFER TO THE SAME CASES AS IN FIG 2

General experience shows that the first reaction (with pepsin) deviates the more from normal the more developed is the stage of cancer—increasing from 3 to 50 per cent An attempt is being made to refine this polarographic diagnosis by experimenting on animals so as to distinguish an early stage of cancer Whilst there are many details still to be investigated in the polarographic reaction of cancer the diagnosis just as it is presented here, offers already substantial advantages over biological tests It is automatically registered and perfectly reproducible the chemical treatment is very simple and comparatively short (one hour standing at room temperature) only 0 5 c c of serum is needed but the reaction may even be carried out with one or two drops (0 1 c c) of blood

Excavations at Njoro, Kenya

By Dr. L S B Leakey

DURING the latter part of April and the beginning of May preliminary excavations were carried out at a small rock shelter in the forest near Njoro, Kenya Colony, and as a result a new branch of the local neolithic stone bowl culture was discovered presenting certain interesting features This small rock shelter had been used during the neolithic period not as a living site but as a place for disposal of the dead by incineration and the particular method which was used in burning the bodies resulted in the preservation of a number of objects not usually found in stone age sites, owing to their perishable nature

The method in which incineration was carried out was to dig a shallow hole in the floor of the shelter, place the body in this in a contracted position, together with a variety of grave goods, cover the whole with soil and red ochre and then light a large fire on top The result of this treatment was that the bodies were baked rather than burnt, while combustible objects such as baskets, cord, woodwork and even calabashes were preserved as charcoal instead of turning to ash

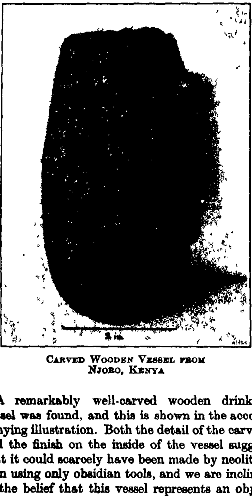
As each successive body was brought to the site to be incinerated a fresh hole was dug into the charred remains of previous burnings which were then disturbed and in course of time the deposit forming the floor of the shelter to a depth of about three feet became composed to a large extent of charcoal and burnt bone Only the bones of the last few bodies incinerated in the shelter before it was abandoned were therefore reasonably intact, and the vast majority of the skulls and skeletons were much broken up

Although only a very small part of the cave floor has been excavated the site had been so extensively used that the remains of more than seventy individuals were recovered Indeed, at one point an area of one cubic yard contained the remains of sixteen individuals

So far as can be stated at present the human remains indicate that the population was very similar to that which I have described in the "Stone Age Races of Kenya as the Elmenteitan type of man , but certain other elements appear to be present also

The human remains, however, are by no means the most interesting of the discoveries at this site, and the chief interest centres around the charred basketry and woodwork and also the many stone beads which were found

Three quite distinct types of basket work were recovered, as well as fragments of a narrow strip of finely woven string fabric which suggest a belt All of these were preserved as charcoal dust, but treatment with 'Durofix' dissolved in amyl acetate proved to be a satisfactory preservative, and the charcoal dust was transformed into a fairly hard substance Large quantities of plaited fibre string and cord were also recovered in the same way.



CARVED WOODEN VESSEL FROM NJORO, KENYA

A remarkably well-carved wooden drinking vessel was found, and this is shown in the accompanying illustration. Both the detail of the carving and the finish on the inside of the vessel suggest that it could scarcely have been made by neolithic man using only obsidian tools, and we are inclined to the belief that this vessel represents an object imported from one of the early civilizations.

While the evidence of the wooden vessel alone would be insufficient ground for postulating a trade with Kenya from one of the early civilizations, this idea is strongly supported by the stone beads. Some five hundred of these as well as a number of beautiful stone pendants were recovered, and they all exhibit a very high degree of workmanship. The semi-precious stones include fire-opals, carnelians, agates (banded and moss varieties) common opals, green quartz and Amazon stone (microcline-felspar). Of these, opals account for more than half the beads. The Amazon stone is of unusually fine quality and at first was mistaken for jade, to which it bears a superficial resemblance.

A variety of shapes of beads occur, including barrels and flat disks, the latter mainly of opal. In all cases the degree of skill shown in shaping and drilling the stone beads and the pendants contrasts strongly with that exhibited in the manufacture of the bone beads and pendants, which were certainly made by the neolithic people concerned, and this again seems to suggest that the former were made by people of superior skill and knowledge.

This view is strengthened by the fact that extensive prehistoric opal mines are connected with this site and in the surrounding area, it is difficult to believe that they were the work of neolithic man for the sake of his personal adornment without a stimulus from outside

On the evidence at present available, therefore, we incline to the view that there was influence from one of the early civilizations which initiated the mining for opals. It is even possible that there was direct contact with the traders, who employed as labour the neolithic inhabitants of the district and paid for the labour with stone beads and pendants

Besides the articles described above, the site yielded a very large number of stone bowls and pestles of a type quite distinct from those belonging to the other branches of the local stone-bowl culture complex, a number of flat grindstones and rubbers, some pottery and also some obsidian implements No trace of metal was found.

It is impossible at present to give a precise date to these new discoveries, but certain indications, such as the method of disposal of the dead, the physical type represented by the skulls and the nature of the obsidian tools all give a definite link with the Elmenteitan mesolithic culture. On the other hand, the stone bowls and pestles are definitely related to those found with other variants of the stone-bowl culture, but they are somewhat cruder typologically.

These facts seem to suggest a date intermediate between the mesolithic and the other neolithic industries previously discovered, and a *very tentative date* of *circa* 4000–3000 B.C. is therefore suggested.

Much will depend on whether the stone beads and pendants and the carved wooden vessel can be definitely linked with any of the early civilizations of the Near East or elsewhere. Any evidence which readers of NATURE can offer bearing on the subject would be greatly appreciated.

Obituary Notices

Dr. A. E. H. Tutton, F.R.S.

ALFRED EDWIN HOWARD TUTTON, who died on July 14, was born on August 22, 1864, at Cheadle Moseley, now the Edgeley district of the borough of Stockport He attended science classes at the Stockport Mechanics Institute and also the evening courses in chemistry of Prof Roscoe at Owens College, Manchester In 1883 he went to the Normal School of Science (later the Royal College of Science) and Royal School of Mines, South Kensington, with an exhibition, which he took in preference to a scholarship which he had gained for Owens College. During his period as a student, Huxley was professor of biology, Frankland of chemistry, Guthrie of physics, Judd of geology and Lockyer of astronomy, and a fellow-student was H. G Wells Tutton was a brilliant student and gained several scholarships and prizes In the meantime, Thorpe had succeeded Frankland as professor of chemistry, and under his direction Tutton began the research on the lower oxides of phosphorus in which the new oxide P_2O_4 was discovered and the lower oxide P_4O_6 was first prepared in a state of purity and definitely characterized in its properties This work was published in 1890 and 1891 In 1889, Tutton had been appointed to the post of demonstrator in chemistry and lecturer in chemical analysis at the College During this period, he also assisted Thorpe and Rucker in the magnetic surveys of Scotland and England.

On the completion of this work, Tutton turned his attention to crystallography, taking some lessons in crystal measurement from Mr H A. (now Sir Henry) Miers, who was then assistant to Prof Story Maskelyne at the British Museum (Natural History) He measured some organic compounds, including aconitine, which had been prepared in the laboratories, but his ambitions were of much wider scope in this subject. He formed a definite plan of research which was to occupy him for forty years, namely, the study of the crystal forms of chemically related series of compounds. These results, he saw, would throw light on the structure of salts, since by replacing one element in a crystalline salt by another, closely related, element, the effects on the molecular volumes and crystal angles of salts which had been generally regarded as isomorphous would be disclosed. It had early been recognized by Wollaston and by Mitscherlich that isomorphism was not absolute, and that small yet definite alterations in crystal angles resulted from the replacement of one isomorphous element by another.

The first series studied by Tutton comprised the sulphates and selenates of potassium, rubidium, cæsium, ammonium and thallium. This was followed by the double sulphates and selenates of these metals with those of magnesium, zinc, iron, nickel, cobalt, manganese, copper and cadmium, which form magnificent crystals with six molecules of water In all, ninety-one salts were studied, and the results communicated in about fifty papers from 1890 until 1929 As a result of this painstaking and accurate work, it was established that the crystallographic properties vary regularly with the atomic weights of the interchangeable elements The same result was established for the perchlorates and double chromates of the alkalis This work could be brought into relation with the structures as revealed by the X-rays when this new method became available In carrying out his crystallographic investigations Tutton showed the greatest ingenuity in devising and perfecting the measuring instruments, so that his methods became well known as representing the highest standard of crystallographic research.

In 1895 Tutton became an inspector of technical schools and moved to Oxford, where he equipped a private laboratory In his ten years in Oxford he became associated with New College and took the B Sc., D Sc and M A degrees, and in 1899 he was elected a fellow of the Royal Society In Oxford he married Miss Margaret Loat. In 1905 he was transferred to the London district and moved his home and laboratory to London. He wrote some important books during this period, his "Crystalline Structure and Chemical Constitution" being published in 1910, "Crystals" in 1911, and "Crystallography and Practical Crystal Measurement" in 1911. The last work, which gives detailed accounts of his practical methods and instruments, appeared in a second edition in two volumes in 1922, and it constitutes one of the most valuable works on experimental crystallography in any language His instruments, he recognized, could be applied to a comparison of the parliamentary and local government copies of the standard of length with the Imperial Standard Yard, and Tutton devised and supervised the construction of an interferential comparator for the Standards Department, the work being carried out in 1907–9. Further work in this direction was curtailed by his transfer to the south western district centred on Plymouth, where he resided at Yelverton, on Dartmoor. His crystallographic researches were continued, although his laboratory was not now so convenient In 1912 he became president of the Mineralogical Society. During the Great War he carried out special work for the Government.

Tutton's services as a lecturer were much sought and he delivered many courses, illustrated by demonstions with his magnificent apparatus. He visited Canada with the British Association in 1909 and spent some time in climbing the Rocky Mountains He also made many visits to the Alps, and in 1927 he published "A Natural History of Ice and Snow, Illustrated from the Alps", enriched by his own photographs. In 1929 he visited Cape Town with the British Association, also going to other parts of

Africa, and returning by way of Egypt and Palestine, which he visited.

In 1930 Tutton had resumed his work on the evaluation of the Imperial Yard in terms of the wave lengths of light. The value, published in 1931 (his last paper), was 1,420,210 wave lengths of the red radiation of cadmium in the yard at 62° F. The value published in 1934 by the National Physical Laboratory, who had used the Fabry-Perot method, was 1,420,209.

In 1924, Tutton moved his house and laboratory to Cambridge, where he participated in the university course in mineralogy at the invitation of Profs. Lewis and Hutchinson. His laboratory during this period was at its best.

Tutton entered into his retirement in 1931, his instruments being transferred to the Physics Department at the University of Manchester, which had conferred on him the honorary degree of D.Sc. in 1926.

Tutton's work stands as an enduring contribution to chemistry and crystallography. Marked by great accuracy and beauty of finish, it was achieved during a life conscientiously devoted to official duties, and hence it exhibits that peculiarly British character which is seen in the researches of other distinguished men of science who have laboured in like circumstances.

J. R. PARTINGTON.

Dr. C. E. Guillaume

BY the recent death of Dr. Charles Edouard Guillaume the world is deprived of a distinguished man of science who had taken a leading part in the advancement of the subject which, for more than fifty years, he had made his own.

His grandfather, Charles Frederic-Alexandre Guillaume, leaving France for political reasons, lived for a time in England, where he established a watch-making business, carried on afterwards by his three sons, of whom Edouard eventually returned to settle at Fleurier, in the Swiss Jura, where Charles Edouard was born on February 15, 1861.

In the course of his education, at the Gymnase in Neuchâtel, and at the Zurich Polytechnic, Guillaume showed a definite bent towards physics and, on leaving, became for a short time an artillery officer, devoting himself with enthusiasm to the study of mechanics and ballistics. So early as 1883, however, he entered the then recently established Bureau International des Poids et Mesures, at Sèvres near Paris, where he was destined to carry out his life's work. Commencing under the successive direction of O. J. Broch and J. R. Benoît, he himself became director of the Bureau in 1915, a position which he held until his retirement, after fifty-three years' service, with the title of honorary director, in 1936.

Guillaume's earliest investigations were concerned with thermometry, an ever-important subject in the science of metrology, and particularly so in the early days of the Bureau, when the new standard metre was being established. Guillaume carried out important investigations on the corrections to mercury-in-glass thermometers, and himself made detailed calibrations of thermometers used at the Bureau in the establishment of the thermal expansions of the standards of length, and for other cognate purposes. He also shared in the initial intercomparisons of the platinum-iridium copies of the International Metre which were prepared for distribution to the various countries subscribing to the Convention du Mètre, and undertook a redetermination of the mass of the cubic decimetre of water, by the method of contact, which gave a result in such excellent agreement with that found by interferential measurements by Chappuis, and by Benoît and Buisson, that it has never been thought necessary since to repeat this measurement.

Guillaume's most important contribution, however, to the science of metrology in particular, and also to industry, was his investigation of the remarkable properties of the nickel-iron alloys. A chance observation, during a search for a suitable alloy less expensive than platinum-iridium to serve as a material for the construction of secondary standards of length, showed that one nickel-iron alloy had a coefficient of thermal expansion above, and another appreciably below, that of either iron or nickel separately. Guillaume at once decided on a systematic investigation of a whole series of alloys, which immediately revealed the general features of the system. Painstaking and exhaustive researches followed, in which he was fortunate to obtain the co-operation of M. Henry Fayol, who put at his disposal the resources of the Aciéries d'Imphy, for the preparation of samples. There resulted the discovery of invar, an alloy with very low (in some cases zero or even slightly negative) coefficient of expansion, 'elinvar', in which the thermal coefficients of linear expansion and elasticity are balanced so as to give constant period of vibration, together with other useful alloys. A complete theory followed of the reversible transformations on which the peculiar properties of these alloys depend.

The introduction of invar rendered practicable the procedure suggested by Jäderin for the use of wires instead of length bars in the measurement of geodetic bases, thus leading to the establishment of the rapid methods in current use for this purpose, and incidentally directly justifying the faith of geodesists by whose insistence largely the Convention du Mètre was originally brought into being. Invar has also been used widely in instrument making and for industrial purposes, for example, for thermostats. In addition, the use both of invar for the pendulums of astronomical clocks and of the 'Guillaume' integral balance with elinvar hair spring, which eliminates secondary errors in high-grade watches and chronometers, has led to a marked advance in the horological industry with which his family was traditionally associated. It is estimated that more than a hundred million watches with 'Guillaume' balances are now in existence.

Throughout his long career, Guillaume was an ardent propagandist for the metric system, and never lost an opportunity for furthering the extension of its application. As director of the Bureau International he had naturally to give much of his time to administrative affairs, and those who had the privilege of meeting and working with him received an impression of outstanding courtesy, tact and charm In addition to other honours and decorations from all over the world, too numerous to mention, he was a Grand Officer of the Legion of Honour, and in 1920 was awarded the Nobel Prize for Physics for his work on the nickel-iron alloys.

WE regret to announce the following deaths ·

Dr. Jan Constantijn Costerus, formerly director of the first High School at Amsterdam, Holland, known for his work on plant teratology, partly with Dr. J. J. Smith, on July 31, aged eighty-nine years

Prof Jacob Kunz, professor of mathematical physics in the University of Illinois, known for his work in astrophysics, on July 18, aged sixty-four years.

Prof Earl B McKinley, dean of the Medical School, director of medical research and professor of bacteriology in the George Washington University, on July 28, aged forty-three years

Mr. F. C. Meier, plant pathologist of the U S. Department of Agriculture, known for his work on the disease of economic fruits, and on ærobiology, on July 28, aged forty-five years

Prof Nicola Parravano, professor of general chemistry in the University of Rome, aged fifty-five years

News and Views

Canadian Tour by Prof. C. D. Ellis, F.R.S.

PROF. C. D ELLIS, who holds the Wheatstone chair of physics at King's College, London, has been granted leave of absence for the Michaelmas and Lent terms in order to visit all the Canadian universities. The tour has been arranged by the Conference of Canadian Universities. The central idea of the scheme is that he should be able to spend some time, up to a week or ten days, in most of the universities, and have ample opportunity for meeting the staff and discussing matters of interest While some formal lectures will be given, it is intended to restrict such to the minimum. By adopting this somewhat unusual but enlightened scheme, the Committee of the Conference of Canadian Universities is showing a very real appreciation of the problems involved in scientific co-operation. A formal lecture, followed by a rapid tour of the laboratories, gives no opportunity of knowing the workers and appreciating their researches. With the more extended visits which Prof Ellis will be able to make, he will have an opportunity of taking a proper share in stimulating discussion Prof. Ellis is leaving England in September, and will go first to Vancouver, and will visit Edmonton, Saskatoon, Winnipeg, Ottawa and Montreal before Christmas. Starting again in January, he will visit Hamilton, London, Toronto, Kingston, Quebec, Sackville, Halifax, returning to England at the end of March.

Dr. J. E. Myers, O.B.E.

DR. J. E. MYERS has been appointed principal of the Manchester College of Technology He was educated at the Manchester Grammar School and at the University of Manchester, where he graduated with first-class honours in chemistry in 1910. Since that date, he has been continuously associated with University teaching and administration as lecturer in chemistry, secretary and tutor to the faculty of science and, more recently, assistant to the vice-chancellor in addition. He has represented the University on numerous bodies connected with higher education, and has been specially interested in student relations, graduate appointments, and the work of the Joint Matriculation Board He obtained the D Sc degree in 1917, and two years later was awarded the distinction of O B E in recognition of scientific work carried out for the Government during the Great War

Robert Warington, F.R.S. (1838–1907)

ON August 22 occurs the centenary of the birth of the English agricultural chemist, Robert Warington, who for many years worked at Rothamsted, Harpenden, Herts, and, like his contemporaries Sir John Lawes and Sir Joseph Gilbert, is buried at Harpenden Warington was the son of Robert Warington (1807–67) the practical chemist who convened the meeting at the Royal Society of Arts on February 23, 1841, which led to the formation of the Chemical Society At this time, Warington's parents were living at the Apothecaries Hall, in the City of London, and as a boy he learned chemistry from his father and from the lectures of Faraday, Brande and Hofmann When twenty years of age, he worked under Lawes at Rothamsted as an unpaid assistant, but a year later he returned to London as assistant to Frankland at South Kensington, whence he went to the Royal Agricultural College, Cirencester It was here that he commenced lecturing on the Rothamsted experiments Leaving Cirencester in 1867, he became chemist to Lawes's manure and acid factory at Millwall, but in 1876 returned to Harpenden, where he remained until 1891, publishing many memoirs on the nitrification of the soil. Leaving the Rothamsted laboratory, he lectured in America, and after his return home was examiner in agriculture to the Science and Art Department and Sibthorpian professor of rural economy at Oxford, a post he held for three years He died at Harpenden on March 20, 1907. His most successful work was his "Chemistry of the Farm", which was translated into several foreign languages and reached its nineteenth edition while he was still alive.

The Problem of Political Refugees

THE conference which opened at Evian on July 6 to discuss the plight of German and Austrian refugees was watched by a great body of opinion in Great Britain in which scientific workers are well represented A letter welcoming the initiative of the Government of the United States in this matter which was sent to President Roosevelt on May 31 bore the signatures of many eminent men of science among other leaders of intellectual life The letter urged that co operation should make it possible to facilitate the transfer of refugees to those countries where their abilities can find most scope, and to provide funds to enable them to make a fresh start, and urged the British Government to play its part both administratively and financially in the support of the great traditions of liberty, tolerance and humanity which it has in common with the United States A further letter to the chairman of the conference urged the importance of immediate, constructive and practical decisions alike on religious, humane and economic grounds if the great democracies are to retain their ancient traditions of freedom and the right of asylum

WHILE none who have welcomed the conference are blind to the difficulties of the situation, even in regard to the admission of skilled professional men and women, still more in what may be called the police problem, the actual outcome of the conference was somewhat disappointing The establishment of a permanent international committee of which, at its first meeting on August 3, when twenty seven countries were represented, Lord Winterton was elected chairman, indicates that within a limited field efforts are being and will continue to be made to deal with this grave problem The committee has prominent American representation, and since it is not a League of Nations organization, it should be easier for it to get in direct touch with all countries responsible for the main refugee problem Moreover, the term 'refugee' has been extended to include persons who, though they may not yet actually have left Germany or Austria, feel obliged to quit those countries as soon as they can because of persecution due to political opinions, religious beliefs, or racial origin While, too, the question of settlement is financial as well as territorial, the democracies have every reason, from their own self-interest as well as that of justice, to support the international committee in any steps it may initiate to bring pressure to bear on the expelling countries to release at least a proportion of the refugees' property to assist in their re-establishment elsewhere

Restoration of the Hurlers, Cornwall

FURTHER work of restoration on the Hurlers, the stone circles near Minions, Cornwall, has been carried out during the past four weeks on behalf of the Office of Works under the supervision of Mr R Ralegh Radford, director of the British School of Archæology at Rome. These circles have been under the guardianship of, and owned by the Office of Works since 1935, when certain preliminary work of investigation and restoration of the central circle was undertaken According to a statement made by Mr Radford (*The Times*, August 12) the recent investigations have been directed to the examination of the northern circle Four stones, additional to the previously known twelve, were found under modern tip heaps, and will be re erected in the original sockets Missing stones will be indicated, as in the central circle, by low stumps inserted in the original positions The damage to the interior of the northern circle by mining test holes and digging will be repaired by filling and levelling A floor of granite fragments similar to that discovered in 1935, washed out of the surface soil, has been discovered covering the greater part of the interior of the circle Its thickness is less than that of the previously discovered floor, this possibility, it is suggested, being due to it having remained in use for a longer period An interesting feature now brought to light is a rough pavement between the northern and central circles, and running along their common axis This pavement is about six feet wide but does not reach out to both circles The suggestion of a ceremonial purpose will, no doubt, be elucidated when examination is completed before the close of the season's work Flint implements, more numerous than in 1935, include several types characteristic of the early metal age, with some of an earlier period Work will be continued in 1939, when it is hoped to restore the monument to its original appearance, so far as that is possible It is also intended to explore the neighbouring barrow, in which the Rillaton gold cup, now in the British Museum, was found This has never been explored scientifically

Roman Dorchester

FURTHER finds of interest are reported from Colliton Park and neighbouring land at Dorchester, where Roman buildings, it will be remembered, have been found on the site which is being prepared for the erection of a county hall The Dorset Archæological Society, which has been responsible for supervising the work in the interests of archæology and for examining finds on the site, has recently made a cutting in Colliton Walk, adjoining the Park, which has brought to light part of the massive walls which once defended the Roman town The walls, it is stated (*The Times*, August 12), were ten feet thick and of solid masonry The ashlar facing has been removed, but the rubble core of flint and limestone, well mortared, still remains The original wall was at least twenty feet high and was banked up internally by a large rampart, on the top of which was a walk for the sentries It is hoped that further investigation may bring to light the foundations of the towers which were a feature of such fortifications The walls at this point were destroyed a hundred years ago, when the walks were laid out , but enough has now been found to show the nature of the original construction In the Park itself, where the site is now in the hands of the contractors, some further remains have been found. Among these is a water conduit, one of the open distributing channels of the Roman system of water supply It is at the bottom of a V-shaped cutting ten feet deep The channel itself is four feet wide, with a bottom of red earthenware tiles No conduit of this type had previously been found in this part of Roman Britain It appears to have gone out of use in the second century A D The foundations of the three roomed Roman building have now been cleared, and show the remarkable and unusually wide doorway, which is seven feet across

Prehistoric Civilization of Northern France

THE party of archæologists deputed by the Society of Antiquaries of London to carry out archæological investigations in northern France is now at work in Brittany and western Normandy under the direction of Dr R E Mortimer Wheeler The expedition has been undertaken with the good will of, and under a permit from the French authorities in accordance with an agreement into which the Society of Antiquaries entered with them last year This investigation will constitute the major undertaking for the time being of the Society in archæological research in the field, taking the place of the excavation of Maiden Castle, Dorchester upon which it was engaged, with Dr Wheeler as its director, for some years The purpose of the investigation in France is to search for evidence of the cross channel origin of the civilization of south western Britain in the later prehistoric period and more especially of the fortified towns which appear there suddenly in a state of mature development but of which the source is uncertain This is a department of investigation in France which French archæologists have left virtually untouched The programme of the investigators is in the first place to map the distribution of pre Roman earthworks of the Maiden Castle type in north western France and secondly to ascertain by trial excavation on selected sites what cultures went to make up these Continental works The first centre which has been chosen for excavation is Huelgoat, a well known site in the pine forest about twenty miles south of Morlaix, where a camp nearly a mile in length is under examination It is seen to have been built in the first century B C on the eve of the Roman conquest of northern France The rampart, fifteen feet high, is faced with stone and bonded with lacing timbers The ditch is in part cut out of the granite rock The search for other sites has progressed so far as to show that the great Wessex fortified sites did not originate in Finistère, though certain smaller fortified enclosures in that department can be paralleled in Cornwall Investigation will shortly move farther east to a large camp in the neighbourhood of Avranches

Fungus Diseases of Animals

A NEW journal devoted to the fungus diseases of man and other animals has recently commenced publication (*Mycopathologia*, Den Haag, Dr W Junk, 18 Dutch florins per volume 1, Fasc 1, 80 pp May 1938) The publication is international, it is edited in Italy and printed in Holland, the United States provides the first number with several authors, whilst the list of collaborators is long and geographically extensive R Ciferri, director of the Botanical Laboratory of the Faculty of Agriculture in the University of Florence, and P Redaelli, director of the Institute of Pathological Anatomy in the University of Padua, are the joint editors They contribute the first paper on "A New Hypothesis on the Nature of *Blastocystis*" This organism shows more affinities with certain algæ than with sporogenous yeasts, and the general biologist will welcome the discovery of a further link between fungi and algæ Classification of fungi belonging to the genus *Actinomyces* is considered by F Baldacci of Padua The rest of the papers in the present number demonstrate the wide scope and outlook of the journal The papers are all scientific contributions to a little known section of mycology, and a Bibliographia Mycopathologia of references to work published in 1937 adds further utility The production is excellent, both of type and plates and the volume should supply a particularly welcome quota of knowledge in Great Britain, where fungal diseases of man are apparently not common enough to provoke research on a large scale

Advances in Printing Telegraph Technique

IT is shown in a paper by A E Thompson, published in *Electrical Communication* of April, that at no period in the history of the telegraph has there been such revolutionary improvements in methods and equipment or such rapid development and expansion in its service to the community as during the last ten years The progress was initiated by the introduction of teleprinter systems which by providing instruments requiring no telegraphic skill on the part of the operators have completely changed the outlook of telegraphy and greatly stimulated development in all its branches Teleprinters are superseding all the older types of machine telegraphic apparatus Even hand Morse working, which has been the backbone of telegraphy for more than a century, has now been abandoned in the British telegraph service, the bulk of the traffic being handled by Creed teleprinters Similar developments are taking place in other countries A description is given of the new Creed No 10 tape teleprinter The improvements achieved are trustworthy service at 85 words per minute, reduced costs, quiet operation and reduced size Maintenance costs have been reduced by evolving mechanisms with a breakdown speed exceeding 100 words per minute The printer operates continuously for 300 hours without requiring lubrication Ball bearings and oil impregnated bearings as well as sliding surfaces lubricated by means of oil reservoirs are used This machine can be used by telegraph administrations and private companies as well as by high speed news and ticker services

History of Maize-Breeding

IN a recent lecture given at the Michigan State College, Mr Henry A Wallace, the United States Secretary of Agriculture, traced the history of maize or corn breeding and pointed out that up to 1890 the farmers of the corn belt had not been superior to their Indian predecessors as corn breeders, the chief improvement having been in substituting a later type of maize for the earlier ones grown by the Indians (Spragg Memorial Lectures on Plant Breeding Eighth Annual Lecture "Corn Breeding Experience and its probable eventual Effect on the Technique of Live stock Breeding" By Henry A Wallace Pp 6 East Lansing, Mich Michigan State College) The application of the genetic methods of Shull and East, that is, inbreeding of strains followed by cross breeding of particular types, has since greatly increased the yield In 1938, probably at least fifteen million acres will be planted, yielding 100 million bushels more than if ordinary open pollinated types were used It is suggested that similar methods applied to animal breeding (that is, homozygosis followed by controlled heterosis), first to egg production in fowls, then to swine, sheep, dairy cows and finally to beef cattle can produce similar results, and the methods of swine breeding in Denmark are cited Mr Wallace concludes that in mankind compulsory sterilization and selection of types under a dictatorship will not bring about the desired eugenic improvement in the human race A standardized preconception of the perfect man, after the Nazi ideal of an Aryan race , is a false eugenic idea which will lead, in the long run, to the failure of eugenic progress

Mexican Pictographic Manuscript

A DOCUMENT of extreme interest to students of American pre Columbian history and culture, the Mendoza Codex, now in the Bodleian Library, has been reproduced in facsimile by Mr J Cooper Clark Captain T A Joyce providing a foreword The Mendoza Codex is one of several pictographic manuscripts which have survived It was prepared by the authority of Don Antonio de Mendoza, who was appointed the first viceroy of New Spain in 1535 The Codex—or rather collection of codices, for there are three—consists of seventy one folio pages, the pictographs being in colour The first part is a copy of an old Mexican chronicle, now lost, of the history year by year of the Lords of Tenochtitlan now Mexico City, and a list of the towns they conquered It covers from A D 1325 until the fall of the Empire in 1521 The second part is a carefully executed copy of the tribute roll to Motecuçuma, the Mexican ruler, by upwards of four hundred towns The original from which this is copied is now in the National Museum of Mexico, and consists of fourteen folios painted on maguey leaves The third part of the Mendoza Codex is a compilation by the scribe for Mendoza s use, recording the life of a Mexican from day to day from the cradle to the grave Although some of the pictures were included by Lord Kingsborough in his book on Mexican art a hundred years ago, this valuable manuscript has never before been reproduced in accurate facsimile as a whole It has now been printed for private publication by Messrs Waterlow on hand made Whatman paper, the pictographs being beautifully reproduced in colour There are three volumes, of which the first contains Mr Cooper Clark's translation of the Spanish text with commentary, the second the interpretation of the Nahuatl place name glyphs, now for the first time rendered in English, and the third volume is the facsimile in colour of the manuscripts The subscription price of the three volumes is twenty guineas

Very Low Temperatures

THE issue by the Science Museum of Books 2 and 3, describing the exhibits and outlining the lectures delivered at the special exhibition devoted to this subject in the Science Museum from March until June last year, completes the account of the exhibition The three books have been edited by Mr T C Crawhall, with the assistance of Dr O Kantorowicz for Book 2 The first book, issued at 6*d* , gives a survey of physical principles and some applications , the second, issued at 2*s* , deals with the apparatus exhibited for temperature reduction, temperature and pressure measurement, liquefaction and solidification of gases, the properties of the products, their storage and their applications Included in the methods of cooling is that of demagnetizing a paramagnetic material The third book, issued at 1*s* 3*d* , gives accounts of the development of low temperature technique, by Prof M Travers, the industrial uses of low temperatures, by Messrs C G Bainbridge, J T Randall and I J Faulkner respectively, and the approach to the absolute zero, by Dr J D Cockroft, Prof F Lindeman and Prof F Simon respectively The three books constitute a valuable record of the present position of a subject which promises to have many applications in industry

Crocodilian Energy

IMPERIAL AIRWAYS inform us that at the end of July, while one of their pilots was taking off in a flying boat at Port Bell on Lake Victoria, a crocodile gave a remarkable display of agility The flying boat had just taken to the air when, about forty yards away, a crocodile about nine feet long leapt full length out of the water, clearing the surface with its whole body by about four feet Apart from its natural history interest, the occurrence was unusual, since, before a flying boat takes off, the surrounding water is most carefully patrolled to guard against possible obstacles, and the flying boats operate as far as possible from areas known to be haunted by crocodiles This unusual air leap of the crocodile is analogous to the leaping of salmon and other fishes, for propulsion is due in both cases to the powerful movements of the tail muscles The size of the individual, a young individual of a species *Crocodilus niloticus*, which may exceed twenty feet in length, illustrates a characteristic of many animals, that the young are notably more nimble than adults

Recent Minor Earthquakes

AFTER the first series of shocks between July 5 and 9 (see NATURE of July 30, p 203), in which buildings were badly cracked in Paliad and Botad though no lives were lost, further tremors have been recorded, and it was reported from Bombay on July 28 that all but the very poorest of inhabitants had deserted the town of Paliad It is rare to find a

VISION IN NATURE AND VISION AIDED BY SCIENCE

Part II

SCIENCE AND WARFARE

by

The Right Hon. Lord Rayleigh, F.R.S.

President of the British Association*

PART I

THE last occasion that the British Association met at Cambridge was in 1904, under the presidency of my revered relative, Lord Balfour, who at the time actually held the position of Prime Minister That a Prime Minister should find it possible to undertake this additional burthen brings home to us how much the pace has quickened in national activities, and, I may add, anxieties, between that time and this

Lord Balfour in his introductory remarks recalled the large share which Cambridge had had in the development of physics from the time of Newton down to that of J J. Thomson and the scientific school centred in the Cavendish Laboratory, "whose physical speculations," he said, "bid fair to render the closing year of the old century and the opening ones of the new as notable as the greatest which have preceded them " It is a great pleasure to me, as I am sure it is to all of you, that my old master is with us here as he was on that occasion. I can say in his presence that the lapse of time has not failed to justify Lord Balfour's words. What was then an intelligent anticipation is now a historical fact.

I wish I could proceed on an equally cheerful note The reputation of the scientific school in the Cavendish Laboratory has been more than sustained in the interval under the leadership of one whose friendly presence we all miss to-night The death of Ernest Rutherford leaves a blank which we can never hope to see entirely filled in our day We know that the whole scientific world joins with us in mourning his loss.

Lord Balfour's address was devoted to topics which had long been of profound interest to him He was one of the first to compare the world picture drawn by science and the world picture drawn by the crude application of the senses, and he emphasized the contrast between them A quotation from his address will serve as an appropriate text to introduce the point of view which I wish to develop.

"So far," he said, "as natural science can tell us, every quality or sense or intellect which does not help us to fight, to eat, and to bring up our children, is but a by-product of the qualities which do. Our organs of sense perception were not given us for purposes of research . . either because too direct a vision of physical reality was a hindrance, not a help in the struggle for existence . . . or because with so imperfect a material as living tissue no better result could be attained."

---

* Presidential address delivered at Cambridge on August 17.

Some of those who learn the results of modern science from a point of view of general or philosophical interest come away, I believe, with the impression that what the senses tell us about the external world is shown to be altogether misleading They learn, for example, that the apparent space-filling quality of the objects called solid or liquid is a delusion, and that the volume of space occupied is held to be very small compared with that which remains vacant in between This is in such violent contrast with what direct observation seems to show that they believe they are asked to give up the general position that what we learn from our senses must be our main guide in studying the nature of things.

Now this is in complete contrast with the point of view of the experimental philosopher He knows very well that in his work he does and must trust in the last resort almost entirely to what can be seen, and that his knowledge of the external world is based upon it · and I do not think that even the metaphysician claims that we can learn much in any other way. It is true that the conclusions of modern science seem at first sight to be very far removed from what our senses tell us But on the whole the tendency of progress is to bring the more remote conclusions within the province of direct observation, even when at first sight they appeared to be hopelessly beyond it

For example, at the time of Lord Balfour's address, some who were regarded as leaders of scientific thought still urged that the conception of atoms was not to be taken literally. We now count the atoms by direct methods. We see the electrometer needle give a kick and we say, "There goes an atom " Or we see the path of an individual atom marked out by a cloud track and we see where it was abruptly bent by a violent collision with another atom

Again, the theory of radioactive decomposition put forward by Rutherford, however cogent it may have seemed, and did seem to those who were well acquainted with the evidence, was originally based on indirect inferences about quantities of matter far too small to be weighed on the most delicate balance Chemists were naturally inclined to feel some reserve , but in due course the theory led to a conclusion which could be tested by methods in which they had confidence—the conclusion, namely, that lead contained in old uranium minerals ought to have a lower atomic weight than ordinary lead, and in all probability to be lighter, and on trying this out it proved to be so. More recently we have the discovery of heavy hydrogen with twice the density of ordinary hydrogen, and heavy water which is the source of it.

Lastly, the conclusion that ordinary matter is not really space-filling has been illustrated by the discovery that certain stars have a density which is a fabulous multiple of the density of terrestrial matter Although this is in some sense a deduction as distinguished from an observation, yet the steps required in the deduction are elementary ones entirely within the domain of the older physics

This and many other points of view have seemed at first sight to contradict the direct indication of our senses But it was not really so They were obtained and could only be obtained by sense indications rightly interpreted As in the passage from Lord Balfour already quoted, the senses were not primarily developed for purposes of research, and we have in large measure to adapt them to that purpose by the use of artificial auxiliaries The result of doing so is often to reveal a world which to the unaided senses seems paradoxical

I have chosen for the main subject of this address a survey of some of the ways in which such adaptations have been made. I shall naturally try to interest you by dwelling most on aspects of the subject that have some novelty ; but apart from these there is much to be gleaned of historical interest, and when tempted I shall not hesitate to digress a little from methods and say something about results

THE HUMAN EYE

I shall begin with a glance at the mechanism of the human eye, so far as it is understood. I shall show how the compromise and balance between different competing considerations which is seen in its design can be artificially modified for special purposes All engineering designs are a matter of compromise You cannot have everything. The unassisted eye has a field of view extending nearly over a hemisphere. It gives an indication very quickly, and allows comparatively rapid changes to be followed. It responds best to the wavelengths actually most abundant in daylight or moonlight. This combination of qualities is ideal for what we believe to be Nature's primary purpose, that is for finding subsistence under primitive conditions, and for fighting the battle of life against natural enemies. But by sacrificing some of these qualities and in particular the large field of view we can enhance others for purposes of research We may modify the lens system by artificial additions over a wide range for examining the very distant or the very small We can supplement and enormously enhance the power of colour discrimination which Nature has given us By abandoning the use of the retina and substituting the photographic plate as an artificial retina we can increase very largely the range of spectrum which can be utilized This last extension has its special possibilities particularly in the direction of using waves smaller than ordinary even down to those which are associated with a moving electron By using the photo electric cell as another substitute for the retina with electric wire instead of optic nerve and a recording galvanometer instead of the brain we can make the impressions metrical and can record them on paper We can count photons and other particulate forms of energy as well We can explore the structure of atoms examine the disintegration of radioactive bodies and trace out the mutual relation of the elements Indeed by elaborating this train of thought a little further almost the whole range of observational science could be covered But within the compass of an hour or so one must not be too ambitious It is not my purpose to stray very far from what might by a slight stretch of language fall under the heading of extending the powers of the eye

Most people who have a smattering of science now know the comparison of the eye with the camera obscura or better with the modern photographic camera—with its lens iris diaphragm focusing adjustment and ground glass screen the latter corresponding to the retina The comparison does not go very far for it does not enter upon how the message is conveyed to the brain and apprehended by the mind or even upon the minor mystery of how colours are discriminated Nevertheless it would be a great mistake to suppose that the knowledge which is embodied in this comparison was easily arrived at For example many acute minds in antiquity thought that light originated in the eye rather than in the object viewed Euclid in his optics perhaps used this as a mathematical fiction equivalent to the modern one of reversing the course of a ray but other authors appealed to the apparent glow of animal eyes by lamplight which shows that they took the theory quite literally The Arabian author Alhazen had more correct ideas and he gave an anatomical description of the eye but apparently regarded what we call the crystalline lens as the light sensitive organ Kepler was the first to take the modern view of the eye

The detailed structure of the retina and its connexion with the optic nerve has required the highest skill of histologists in interpreting difficult and uncertain indications The light sensitive elements are of two kinds the rods and cones The rods seem to be the only ones used in night vision and do not distinguish colours The cones are most important in the centre of the field of view where vision is most acute and it seems to be fairly certain that in the foveal region each cone has its own individual nervous communication with the brain On the other hand there is not anything like room in the cross section of the optic nerve to allow us to assign a different nerve fibre to each of the millions of rods A single fibre probably has to serve two hundred of them

The nervous impulse is believed to travel in the optic nerve as in any other nerve but what happens to it when it arrives at the brain is a question for the investigators of a future generation

Use of Lenses

The use of lenses is one of the greatest scientific discoveries we do not know who made it Indeed the more closely we inquire into this question the vaguer it becomes Spectacle lenses as we know them are a medieval invention dating from about A D 1280 Whether they originated from some isolated thinker and experimenter of the type of Roger Bacon or whether they were developed by the ingenuity of urban craftsmen can scarcely be considered certain There are several ways in which the suggestion might have arisen but a glass bulb filled with water is the most likely Indeed considering that such bulbs were undoubtedly used as burning glasses in the ancient world and that the use of them for reading small and difficult lettering is explicitly mentioned by Seneca it seems rather strange that the next step was not taken in antiquity Apparently the explanation is that the magnification was attributed to the nature of the water rather than to its shape At all events it may readily be verified that a 4 or 5 inch glass flask full of water though not very convenient to handle will give a long sighted newspaper reader the same help that he could get from a monocle

The invention of lenses was a necessary preliminary to the invention of the telescope for as Huygens remarked it would require a superhuman genius to make the invention theoretically

The retina of the eye on which the image is to be received has structure We may compare the picture on the retina to a design embroidered in woolwork which also has a structure Clearly such a design cannot embody details which are smaller than the mesh of the canvas which is to carry the coloured stitches The only way to get in more detail is to make the design or rather such diminished part of it as the canvas can accommodate on a larger scale Similarly with the picture on the retina The individual rods and cones correspond with the individual meshes of the canvas If we want more detail of an object we must make the picture on the retina larger with the necessary sacrifice of the field of view If the object is distant we want for this a lens of longer focus instead of the eye lens We cannot take the eye lens away but what amounts to nearly the same thing we can neutralize it by a concave lens of equal power put right up to it called the eye piece Then we are free to use a long focus lens called the telescopic objective to make a larger picture on the retina It must of course be put at the proper distance out to make a distinct picture This is a special case of the Galilean telescope which lends itself to simple description It is of no use to make the picture larger if we lose definition in the process The enlarged image must remain sharp enough to take advantage of the fine structure of the retinal screen that is to receive it It will not be sharp enough unless we make the lens of greater diameter than the eye Another reason for using a large lens is to avoid a loss of brightness

It seems paradoxical that the image of a star should be smaller the larger the telescope Nevertheless it is a necessary result of the wave character of light We cannot see the true nature of for example a double star unless the two images are small enough not to overlap and far enough apart to fall on separated elements of the observer s retina

When the problem is to examine small objects we look at them as close as we can here the short sighted observer has an advantage By adding a lens in front of the eye lens to increase its power we can produce a kind of artificial short sight and get closer than we could otherwise so that the picture on the retina is bigger This is a simple microscope and we can use it to examine the image produced by an objective lens if this image is larger than the object under examination we call the whole arrangement a compound microscope

Given perfect construction there is no limit in theory to what a telescope can do in revealing distant worlds It is only a question of making it large enough On the other hand there is a very definite limit to what the miscroscope used with say ordinary daylight can do It is not that there is any difficulty in making it magnify as much as we like This can be done for example by making the tube of the microscope longer The trouble is that beyond a certain point magnification does no good Many people find this a hard saying but it must be remembered that a large image is not necessarily a good image We are up against the same difficulty as before A point on the object is necessarily spread out into a disk in the image due to the coarseness of structure of light itself as indicated by its wave length I cannot go into the details but it is well known that points on the object which are something less than half a wave length or say a one hundred thousandth or an inch apart cannot be distinctly separated This is the theoretical limit for a microscope using ordinary light and it has been practically reached The early microscopists would have thought this more than satisfactory but the limit puts a serious obstacle in the way of biological and medical progress to day For example the pathogenic bacteria in many cases are about this size or less and there is special interest in considering in what directions we may hope to go further

Since microscopic resolution depends on having a fine structure in the light itself something though not perhaps very much may be gained by the use of ultra violet light instead of visible light It then becomes necessary to work by photography We are nearing the region of the spectrum where almost everything is opaque In the visual region nearly every organic structure is transparent and to get contrast stains have to be used which colour one part more deeply than the other In the ultra violet on the other hand we get contrast without staining and as Mr J E Barnard has shown the advantage lies as much in this as in the increased resolving power For example using the strong ultra-violet line of the mercury vapour lamp which has about half the wave length of green light he finds that a virus contained within a cell shows up as a highly absorptive body in contrast with the less absorptive elements of the cell. So that ultra-violet microscopy offers some hope of progress in connexion with this fundamental problem of the nature of viruses

With ultra-violet microscopy we have gone as far as we can in using short waves with ordinary lenses made of matter, for the available kinds of matter are useless for shorter waves than these, and it might well seem that we have here come to a definite and final end Yet it is not so There are two alternatives, which we must consider separately Paradoxical as it may seem, for certain radiations we can make converging lenses out of empty space , or alternatively we can make optical observations without any lenses at all

THE ELECTRON MICROSCOPE

The long-standing controversy which raged in the nineties of the last century as to whether cathode rays consisted of waves or of electrified particles was thought to have been settled in favour of the latter alternative But scientific controversies, however acutely they may rage for a time, are apt, like industrial disputes, to end in compromise , and it has been so in this instance According to our present views the cathode rays in one aspect consist of a stream of electrified particles , in another, they consist of wave trains, the length being variable in inverse relation to the momentum of the particles

Now cathode rays have the property of being bent by electric or magnetic forces, and far-reaching analogies have been traced between this bending and the refraction of light by solids , indeed, a system of 'electron optics' has been elaborated which shows how a beam of cathode rays issuing from a point can be reassembled into an image by passing through a localized electrostatic or magnetic field having axial symmetry This constitutes what has been called an electrostatic or magnetic lens It is then possible to form a magnified image of the source of electrons on a fluorescent screen, and that is the simplest application But we can go further and form an image of an obstructing object such as a fine wire by means of one magnetic lens, acting as objective, and amplify it by means of a second magnetic lens, which is spoken of as the eyepiece, though of course it is only such by analogy, for the eye cannot deal directly with cathode rays. The eyepiece projects the image on to a fluorescent screen, or photographic plate.

So far we have been thinking of the electron stream in its corpuscular aspect But we must turn to the wave aspect when it comes to consideration of theoretical resolving power The wave-length associated with an electron stream of moderate velocity is so small that if the electron microscope could be brought to the perfection of the optical microscope, it should be able to resolve the actual atomic structure of crystals This is very far indeed from being attained, the present electron microscope being much further from its own ideal than were the earliest optical microscopes Nevertheless, experimental instruments have been constructed which have a resolving power several times better than the modern optical microscope The difficulty is to apply them to practical biological problems

It is not to be supposed that the histological technique so skilfully elaborated for ordinary microscopy can at once be transferred to the electron microscope For example, the relatively thick glass supports and covers ordinarily used are out of the question Staining with aniline dyes is probably of little use, and the fierce bombardment to which the delicate specimen is necessarily exposed will be no small obstacle Certain standard methods, however, such as impregnation with osmium, seem to be applicable and there is some possibility that eventually the obscure region between the smallest organisms and the largest crystalline structure may be explored by electron microscopy

USE OF X-RAYS

In referring to the limitations on the use of lenses, I mentioned the other alternative that we might, in order to work with the shortest waves, dispense with lenses altogether and in fact in using X rays this is done We are then limited to controlling the course of the rays by means of tubes or pinholes This restriction is so serious that it altogether defeats the possibility of constructing a useful X-ray microscope analogous to the optical or the electron microscope In spite of this, the use of X-rays is of fundamental value for dealing with a particular class of objects, namely, crystals, which themselves have a regular spacing, comparable in size with the length of the waves Just as the spacing of a ruled grating (say 1/20,000 of an inch) can be compared with the wave-length of light by measuring the angle of diffraction, so the spacing of atoms in a crystal can be compared with the wave-length of X-rays But here the indications are less direct than with the microscope, and depend on the object having a periodic structure So that the method scarcely falls within the scope of this address How essential the difference is will appear if we consider that the angle to be observed becomes greater and not less the closer the spacing of the object under test

COLOUR

Colour vision is one of Nature's most wonderful achievements, though custom often prevents our perceiving the wonder of it We take it for granted that anyone should readily distinguish the berries on a holly bush, and we are inclined to be derisive of a colour-blind person who cannot do so But so far anatomy has told us little or nothing of how the marvel is achieved Experiments on colour vision show that three separate and fundamental colour sensations exist It is probable that the cones of the retina are responsible for colour vision, and the rods for dark-adapted vision which does not discriminate colour But no division of the cones into three separate kinds corresponding to the three colour sensations has ever been observed Nor is any anatomical peculiarity known which allows a colour-blind eye to be distinguished from a normal one

Can artificial resources help to improve colour discrimination? In some interesting cases they can Indeed, the whole subject of spectroscopy may be thought of as coming under this head We can recognize the colour imparted by sodium to a flame without artificial help When potassium is present as well, the red colour due to it can only be seen when we use a prism to separate the red image of the flame from the yellow one Such a method has its limitations, because if the coloured images are more numerous they overlap, and the desired separation is lost To avoid this, it is necessary to make a sacrifice, and to limit the effective breadth of the flame by a more or less narrow slit, and if the images are very numerous the slit has to be so narrow that all indication of the breadth of the source is lost This, of course, is substantially the method of spectroscopy, into which I do not enter further

There is an interesting class of cases, however, where we cannot afford to sacrifice the form of the object entirely to colour discrimination Consider, for example, the prominences of the sun's limb, which are so well seen against the darkened sky of an eclipse, but are altogether lost in the glare of the sky at other times. In order to see them, prismatic dispersion is made use of, and separates the monochromatic red light of hydrogen from the sky background A slit must be used to cut off the latter but if it is too narrow the outlines of the prominence cannot be seen By using a compromise width, it is possible to reconcile the competing requirements in this comparatively easy case. Indeed, M B Lyot, working in the clear air of the observatory of the Pic du Midi, where there is less false light to deal with, has even been able to observe the prominences through a suitable red filter, which enables the whole circumference of the sun to be examined at once, without the limitations introduced by a slit

A much more difficult problem is to look for bright hydrogen eruptions projected on the sun's disk, and at first sight this might well seem hopeless. A complete view of them was first obtained by photography, but I shall limit myself to some notice of the visual instrument perfected by Hale and called by him the spectrohelioscope A very narrow slit has to be used, and hence only a very small breadth of the sun's surface can be seen at any one instant But the difficulty is turned by very rapidly exposing to view successive strips of the sun's surface side by side The images then blend, owing to persistence of vision, and a reasonably broad region is included in what is practically a single view I must pass over the details of mechanism by which this is carried out

There are now a number of spectrohelioscopes in different parts of the world, and a continuous watch is kept for bright eruptions of the red hydrogen lines Already these are found to be simultaneous with the 'fading' of short radio waves over the illuminated hemisphere of the earth, and the brightest eruptions are simultaneous with disturbances of terrestrial magnetism At the Mount Wilson Observatory, such eruptions have been seen at the same time at widely separated points on the sun, indicating a deep-seated cause. There are therefore very interesting and fundamental questions within the realm of this method of investigation

THE PHOTOGRAPHIC PLATE

We have so far been mainly considering how we may adapt our vision for objects too small or too far off for unassisted sight, and for colour differences not ordinarily perceptible This is chiefly done by supplementing the lens system of the eye by additional lenses or by prisms We cannot supplement the retina, but in certain cases we can do better We can substitute an artificial sensitive surface which may be either photographic or photo-electric

That certain pigments are bleached by light is an observation that must have obtruded itself from very early times—indeed, it is one of the chief practical problems of dyeing to select pigments which do not fade rapidly If a part of the coloured surface is protected by an opaque object —say a picture or a mirror hanging over a coloured wallpaper—we get a silhouette of the protecting object, which is in essence a photograph

Again, it is a matter of common observation that the human skin is darkened by the prolonged action of the sun's light, and here similarly we may get what is really a silhouette photograph of a locket, or the like, which protects the skin locally In this case we are perhaps retracing the paths which Nature herself has taken for the evolution of the eye is regarded as having begun with the general sensitiveness to light of the whole surface of the organism

The sensitivity of at all events the dark-adapted eye depends on the accumulation on the retinal rods of the pigment called the visual purple, of which the most striking characteristic is its ready bleaching by light We can even partially fix' the picture produced in this way on the retina of, for example, a frog by means of alum solution This brings home to us how clearly akin are the processes in the retina to those in the photographic plate, even though the complexity of the former has hitherto largely baffled investigation

There are then many indications in Nature of substances sensitive to light, and quite a considerable variety of them have from time to time been used in practical photographic processes But compounds of silver, which formed the basis of the earliest processes, have maintained the lead over all others The history of photography by means of silver salts cannot be considered a good example of the triumph of the rational over the empirical. For example, the discovery of developers came about thus The first workers, Wedgewood and Davy (1802), had found that they got greater sensitivity by spreading the silver salt on white leather instead of paper. An early experimenter, the Rev. J. B. Reade (1837), was anxious to repeat this experiment, and sacrificed a pair of white kid gloves belonging to his wife for the purpose. When he wished to sacrifice a second pair, the lady raised a not unnatural objection, and he said, "Then I will tan paper " He treated paper with an infusion of oak galls and found that this increased the sensitivity greatly It amounted to what we should call exposing and developing simultaneously. But, in using the method, it is easily observed that darkening continues after exposure is over, and this leads to beginning development after the exposure This step was taken by Fox Talbot a year or two afterwards Instead of crude infusion of galls he used gallic acid Later, pyrogallic acid was used instead of gallic acid, and still survives

The use of gelatine as a medium to contain the silver halide was a more obvious idea. But it was not so easy to foresee that the sensitivity of silver salts would be much further increased when they were held in this medium For long this remained unexplained, until it was noticed that some specimens of gelatine were much more active than others This was ultimately traced by S E Sheppard to the presence of traces of mustard oil, a sulphur compound, in the more active specimens This, in turn, depends in all probability on the pasturage on which the animals that afford the gelatine have been fed The quantity present is incredibly small, comparable in quantity with the radium in pitchblende

The value to science as well as to daily life of the gelatine dry plate or film can scarcely be overestimated Take, for example, the generalized principle of relativity, which attempts with considerable success to reduce the main feature of the cosmical process to a geometrical theory The crucial test requires us to investigate the gravitational bending of light, by photographing the field of stars near the eclipsed sun For this purpose, the gelatine dry plate has been essential and here, as we have seen, we get into complicated questions of biochemistry This is to my mind a beautiful example of the interdependence of different branches of science and of the disadvantages of undue specialization (or should I say generalization ?) We may attempt to reduce the cosmos to the dry bones of a geometrical theory, but in testing the theory we are compelled to have recourse again to the gelatine which we have discarded from the dry bones !

To come back, however, to the development of the photographic retina, as I may call it. As is well known, the eye has maximum sensitivity to the yellow green of the spectrum but ordinary silver salts are not sensitive in this region. Their maximum is in the blue or violet, and ranges on through ultra violet to the X ray region. It was not at all easy to extend it on the other side through green, yellow and red to infra red. The story of how this was ultimately attained is one more example in the chapter of accidental clues skilfully followed up which forms the history of this subject.

In 1873, Dr Hermann Vogel of Berlin noticed that certain collodion plates of English manufacture which he was using for spectrum photography, recorded the green of the spectrum to which the simple silver salts are practically insensitive. The plates had been coated with a mixture which contained nitrate of uranium, gum, gallic acid and a yellow colouring matter. What the purpose of this coating was is not very obvious. It rather reminds one of medieval medical prescriptions which made up in complexity what they lacked in clear thinking. But Vogel concluded with true scientific insight that it must owe the special property he had discovered to some constituent which absorbs the green of the spectrum more than the blue, for conservation of energy requires that the green should be absorbed if it is to act on the plate. He then tried staining the plate with coralline red which has an absorption band in the green with the expected result. With much prescience he says: "I think I am pretty well justified in inferring that we are in a position *to render bromide of silver sensitive for any colour we choose*. Perhaps we may even arrive at this, namely photographing the ultra red as we have already photographed the ultra violet." It was, however, half a century before this far seeing prophecy was fully realized. The development of the aniline colour industry gave full scope for experiment, but it has been found by bitter experience that dyes which can produce the colour sensitiveness are often fatal to the clean working and keeping qualities of the plate. However, success has been attained, largely by the efforts of Dr W. H. Mills, of the chemical department of the University of Cambridge, and of Dr C. E. K. Mees, of the Kodak Company, and we all see the fruits of it in the photographs by lamplight which are often reproduced in the newspapers.

It is now known in what direction the molecular structure of the sensitizing dye must be elaborated in order to push the action further and further into the infra-red, and the point when water becomes opaque has nearly been reached, with great extension of our knowledge of the solar spectrum. The spectra of the major planets have also been extended into the infra red, and this has given the clue as to the true origin of the mysterious absorption bands due to their atmospheres which had baffled spectroscopists for more than a generation. These bands have been shown by Wildt to be due to methane or marsh gas. Neptune, for example, has an atmosphere of methane equivalent to 25 miles thickness of the gas under standard conditions. In this Neptunian methane we have a paraffin certainly not of animal or vegetable origin, and I venture in passing to make the suggestion that geologists might usefully take it into consideration in discussing the origin of terrestrial petroleum.

PHOTO ELECTRIC SURFACES

The photographic plate is not the only useful substitute for the human retina. We have another in the photo electric surface. The history of this discovery is of considerable interest. Heinrich Hertz in his pioneering investigation of electric waves (1887), made use of the tiny spark which he obtained from his receiving circuit as an indicator. His experiments were done within the walls of one room. When he boxed in the indicating spark so as to shield it from daylight and make it easier to see, he found that this precaution had exactly the opposite effect—the spark became less instead of more conspicuous. To express it shortly and colloquially, this action was found to depend on whether or not the spark of the receiver could see the spark of the oscillator. Moreover, seeing through a glass window would not do. It was ultra violet light from the active spark that influenced the passive spark. Further, Hertz was able to determine that the action occurred mainly, if not entirely, at the cathode of the passive spark.

The next step was taken by Hallwachs, who showed that it was not necessary to work with the complicated conditions of the spark. He found that a clean zinc plate negatively charged rapidly lost its charge when illuminated by ultra violet light.

The final important step was in the use of a clean surface of alkali metal *in vacuo*, which responds to visible light, and passes comparatively large currents. This constitutes the photo-electric cell very much as we now have it, and was due to two German schoolmasters, J. Elster and

H Geitel English physicists who met them during their visit to Cambridge a generation ago will not fail to have agreeable memories of their single-minded enthusiasm and devoted mutual regard Sir J J Thomson has recalled them to our recollection in his recent book. They could scarcely have foreseen that their work, carried out in a purely academic spirit, would make possible the talking films which give pleasure to untold millions

The sensitiveness of the dark-adapted eye has often been referred to as one of its most wonderful features ; but, under favourable conditions, the sensitivity of a photo-electric surface may even be superior According to our present ideas, no device conceivable could do more than detect every quantum which fell upon it Neither the eye nor the photo-electric surface comes very near to this standard, but it would seem that the falling short is rather in detail than in principle The action of the photo-electric cell depends on the liberation of an electron by one quantum of incident energy, and under favourable conditions the liberation of one electron can be detected, by an application of the principle of Geiger's counter The action of the dark-adapted eye depends on the bleaching of the visual purple According to the results of Dartnell, Goodeve and Lythgoe, it appears likely that one quantum can bleach a molecule of this substance, and in all probability this results in the excitation of a nerve fibre which carries its message to the brain

The photo-electric cell can be used like the photographic plate at the focus of an astronomical telescope It might seem from the point of view of evolution a retrograde step to substitute a single sensitive element for the 137 million such elements in the human eye In this connexion, it is interesting to note that, in certain invertebrate animals, eyes are known which have the character of a single sensitive element, with a lens to concentrate the light upon it Such an eye can do little more than distinguish light from darkness But its artificial counterpart using the photo-electric surface has the valuable property that the electric current which indicates that light is falling upon it can be precisely measured, so as to determine the intensity of the light. In contrast with photographic action, the energy available to produce the record comes not from the original source of light, which only, as it were, pulls the trigger, but from the battery in the local circuit, and it may be amplified so as to actuate robust mechanisms. It has been applied with success to guiding a large telescope or, in a humbler sphere, to open doors, or even to catch thieves

However, the scientific interest lies more in the possibility of accurate measurement As an interesting example we might take the problem of measuring the apparent diameter of the great nebula in Andromeda As is known, modern research tends to indicate that the Andromeda nebula and other like systems are the counterparts of the galaxy, being in fact island universes But until lately there was such a serious difficulty in that all such systems appeared to be considerably smaller than the galaxy Stebbins and Whitford, by traversing a telescope armed with a photo-electric cell across the nebula, have found that its linear dimensions were twice as great as had been supposed, reducing the discrepancy of size to comparatively little

TELEVISION

But, it may be suggested, could we not go further and make a photo electric equivalent, not only for the rudimentary kind of eye, which has only a single sensitive element, but also for the developed mammalian eye, which has an enormous number ? Could we not build up on separated photo-electric elements a complete and detailed picture ? In point of fact this has been done in the development of television , and since this new art which interests us all can properly be considered as an extension of the powers of normal vision, no excuse is needed for devoting some consideration to it

We must divide the photo-electric surface into minute patches which are electrically insulated from one another This is not too difficult , but if it were proposed directly to imitate Nature, and attach a wire, representing a nerve fibre, to each of these patches, so as to connect it to the auxiliary apparatus, we might well despair of the task , for there are probably half a million such connexions between the human retina and the brain. In the artificial apparatus for television, one single connexion is made to serve, but it is in effect attached to each of the patches in rapid succession by the process of 'scanning' the image The photo-electric mosaic is on one side of a thin mica sheet, and a continuous metal coating on the other side gives the connexion, which is by electrostatic induction Each element of the surface forms a separate tiny condenser with the opposing part of the back plate.

Scanning is achieved by rapidly traversing a beam of electrons over the mosaic line by line The whole surface, and therefore each element must be scanned at least twenty times a second In the intervals an element is losing electrons more or less rapidly The scanning beam comes along, and restores the lost electrons discharges the little condenser formed by the element and the back plate, and sends an electric signal into the wire attached to this plate The strength of this signal will depend on how many electrons the element had lost since the previous scanning and thus on the luminous intensity of that part of the image An important point is that the element is in action all the time and not only while it individually is being scanned

We have thus transmuted the momentary picture into a series of electric pulses occupying in all a time of one twentieth of a second and these can be amplified and sent out as wireless signals How are they to be turned back again into a visible picture at the other end ? Well that is not, perhaps, so difficult as the first conversion of the picture into signals We must make a beam of electrons follow and imitate the periodic movements of the scanning beam at the other end The beam of electrons falls on a luminescent screen, and makes it light up more or less brightly according to the intensity of the electron beam If we use the incoming signals to modulate the electron beam, we can make them correspond with the intensities at the sending end, and the original picture is reconstructed piece by piece The reconstruction is completed in one twentieth of a second or less and the process begins again The successive pictures blend into one another as in the cinema, and movement is shown with apparent continuity

It seems not unlikely that the electric eye or iconoscope, as it has been called, may have applications apart from television Dr V K Zworykin, who took an important part in its development, suggested that it might be used to make visible the image in the ultra violet microscope, which would be much too faint for direct projection on a fluorescent screen For that purpose the sending and receiving apparatus would of course, be connected directly, without radio transmission It might also be used for rapid photography, if the photographic plate replaced the viewing screen The beauty of the device is that the energy is supplied locally, the distant light source merely releasing it The principle of amplification may thus perhaps be applied to the photographing of faint objects

I come to the close of this part of my subject Much of modern scientific doctrine appears at first sight to have an elusive and even metaphysical character and this aspect of it seems to make the strongest appeal to many cultivated minds Yet upon the whole, the main triumphs of science lie in the tangible facts which it has revealed , and it is these which will without doubt endure as a permanent memorial to our epoch My main thesis has been that these are discovered by methods not essentially different from direct scrutiny It is hoped that the present survey may remind you that if we allow for a reasonable broadening of the original meaning of the words, it remains true, after all that seeing is believing '

PART II

During the Great War itself few scientific men in any country doubted that it was their duty to do what they could to apply their specialized knowledge to the purposes of war nor was it often suggested by publicists that there was any countervailing consideration on the contrary, they urged strongly that our resources in this direction should be efficiently mobilized It is chiefly in vague general discussions that the opposite view becomes vocal

Science, it is urged, is the source of all the trouble and we may look to scientific men for some constructive contribution to finding a remedy It is worth while to inquire what basis there is for this indictment, and whether in fact, it is feasible for men of science to desist from labours which may have a disastrous outcome, or at any rate to help in guiding other men to use and not to abuse the fruits of those labours I may say at the outset that I have no sanguine contribution to make I believe that the whole idea that scientific men are specially responsible is a delusion born of imperfect knowledge of the real course of the process of discovery Indeed, very much the same complaint was made before the scientific era Let me refer you to Shakespeare's play, "Henry IV"

> "Great pity, so it was
> This villainous saltpetre should be digged
> Out of the bowels of the harmless earth
> Which many a good tall fellow had destroyed
> So cowardly "

The quotation leads us to inquire how far the further development of this particular kind of frightfulness into modern high explosives was deliberate or not

In the course of systematic study of the chemistry of carbon compounds it was inevitable that the action of nitric acid on substances like benzene toluene glycerine cellulose and the like should be tried No one could foresee the result In the case of benzene we have nitrobenzene the key to the aniline dye industry In the case of glycerine Sobrero obtained in 1846 the highly explosive liquid called nitro glycerine He meant no harm and in fact his discovery lay dormant for many years until Nobel turned his attention to the matter in 1863 and showed how by mixing nitro glycerine with other substances solid explosives could be made which admitted of safe handling Dynamite was one of them They proved invaluable in the arts of peace for example in mining and in making railway tunnels such as those through the Alps They were used by the Irish Fenians in the dynamite outrages of the eighties These attempted outrages were not very successful and so far as I know no one was inclined to blame science for them any more than for the Gunpowder Plot Like the latter they came to be considered slightly comic If anyone doubts this he may agreeably resolve his doubts by reading R L Stevenson s story The Dynamiter At all events high explosives had been too long in use in peaceful industry for their misuse to be laid directly to the account of science

Coming next to poison gas We read that Pliny was overwhelmed and killed by sulphur dioxide in the eruption of Vesuvius in A D 79 During the Crimean War the veteran admiral Lord Dundonald urged that the fumes of burning sulphur should be deliberately used in this way but the suggestion was not adopted Even if it had been scientific research *ad hoc* would obviously have had little to do with the matter During the Great War chlorine was used on a large scale I need scarcely insist that chlorine was not isolated by chemists for this purpose It was discovered a hundred and forty years before as a step in the inquiry into the nature of common salt

Coming to the more recondite substances we may take mustard gas—really a liquid—as typical It is much more plausible to suggest that here was a scientific devilment deliberately contrived to cripple and destroy But what are the real facts ?

Referring to Watts s Dictionary of Chemistry (edition of 1894) there is an article of less than forty words about mustard gas (under the heading of dichlordiethyl sulphide) After the method of preparation used by Victor Meyer has been mentioned the substance is dismissed with the words *oil very poisonous and violently inflames the skin Difference from diethyl sulphide*

There are sixteen other compounds described at comparable length on the same page So far as I know none of them is of any importance A not uncommon type of critic would probably say that the investigation of them had been useless the work of unpractical dreamers who might have been better employed One of these substances namely mustard gas is quite unexpectedly applied to war and the production of it is held by the critics to be the work not of dreamers but of fiends whose activities ought to be suppressed !

Finally at the bottom of the page begins a long article on chloroform This substance as you know has relieved a great deal of pain and on the same principle the investigator who produced it was no doubt an angel of mercy The trouble is that all the investigators proceeded in exactly the same spirit the spirit that is of scientific curiosity and with no possibility of telling whether the issue of their work would prove them to be fiends or dreamers or angels

Again there is the terror of thermite incendiary bombs spreading fire broadcast throughout great cities The notion is sometimes encountered that thermite was invented for this purpose Nothing could be further from the truth I first made acquaintance with it myself in 1901 by hearing a lecture at the Royal Institution by the late Sir William Roberts Austen on Metals as Fuel He directed attention to the great amount of energy which was liberated when aluminium combined with oxygen and showed how aluminium powder mixed with red oxide of iron would react violently with it withdrawing the oxygen from the iron and becoming brilliantly incandescent in the process He showed further how this mixture called thermite could be used for heating metal work locally so as to make welds for example in joining two iron pipes end to end I venture to say that it never occurred to him or to any of his hearers that thermite had any application in war

In discussions of this kind a distinction is often implied between what I may call old fashioned knowledge and modern scientific knowledge The latter is considered to be the special handmaid of frightfulness The futility of this distinction is easily seen by considering a special case Iron is thought of as belonging to the pre scientific era while aluminium is thought to belong to the scientific era From the point of view of chemistry both are metals and the problem of producing them in either case is a chemical one When produced they both have their function in frightfulness' iron to cut and stab aluminium to make thermite bombs to burn and destroy If modern science makes its contribution to frightfulness in giving us aluminium ancient craft did so in giving us iron It is obviously absurd to make any distinction in principle between the two cases Science properly understood includes all real knowledge about material things whether that knowledge is old or new

All these terrors have only become applicable against a civilian population by the development of aircraft Military objects were certainly not the incentive of the successful pioneers of artificial flight They were fascinated at first by the sport of gliding and afterwards by a mechanical transport problem

It is true that brilliant writers of imaginative fiction such as Jules Verne and H G Wells had foretold all and more than all the horrors that have since come to pass But it is perhaps more to the point to inquire what were the contemporary views of practical men The Wrights made their first successful flight in 1903 In 1904 I myself heard the then First Sea Lord of the Admiralty repudiate with scorn the suggestion that the Government were interesting themselves in the matter and I know with equal definiteness that even so late as 1908 the Chief of the Imperial General Staff did not believe in the military importance of flight Would it be fair then to blame the inventors for not having realized it and for not having stayed their hands ?

Summing up what may be learnt from the experience of the past I think we may say that the application of fundamental discoveries in science to purposes of war is altogether too remote for it to be possible to control such discoveries at the source

For good or ill the urge to explore the unknown is deep in the nature of some of us and it will not be deterred by possible contingent results which may not be and generally are not fully apparent until long after the death of the explorer The world is ready to accept the gifts of science and to use them for its own purposes It is difficult to see any sign that it is ready to accept the advice of scientific men as to what those uses should be

Can we then do nothing ? Frankly I doubt whether we can do much but there is one thing that may be attempted The British Association has under consideration a division for study of the social relations of science which will attempt to bring the steady light of scientific truth to bear on vexed questions We rejoice to know that our distinguished American visitors are in sympathy with this aim and we hope that our discussions with them will bear useful if modest fruit in promoting international amity

SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS *

Logic and Probability in Physics

AFTER paying a short tribute to the memory of Lord Rutherford, the president of Section A (Mathematical and Physical Sciences), Prof C G Darwin, comes to his main subject, which is the inadequacy of the reasoning processes which have in the past been regarded as the proper machinery of scientific thought We have set up as the ideal form of reasoning the formal logic of Aristotle, we rarely conform to this ideal, but instead we make use of arguments having no accurate axiomatic basis, which compel belief because of some large accumulation of favourable evidence The old logic was devised for a world that was thought to have hard outlines, and now that we know that the outlines are not hard the method of reasoning must be changed The key to the modification lies in probability, but whereas in the past it was expected that probability could somehow be fitted into the old logic, the attempt has always failed, and we must recognize it as an independent principle. Our instincts only accept this with difficulty, but a similar unsatisfying state of affairs used to exist in mechanics, which has been over come by the quantum theory, and an analogy may be developed between the two cases

There follows a review of the history of the quantum theory, touching on a number of points of interest, but having special reference to the way in which it has dealt with causality The old mechanics seemed to point with all the compulsive force of a logical syllogism to absolute determinism We are still scarcely free from the feeling of this compulsion, but we know it is wrong, and we know where the fault lay. An analogy may be made between this state of affairs and our feeling about the place of probability in logic We used to feel that classical mechanics provided no room for anything outside itself, and we feel that the old logic is the only really admissible form of reasoning. Certain things refused to fit into the classical scheme and led to the old quantum theory, and we have found that the old logic is inadequate without the supplementary principle of probability. In mechanics the union is completed by the new quantum theory, but we have not yet satisfactorily blended our reasoning principles.

The sort of way the union may come about is suggested by another branch of physical theory, the kinetic theory of gases One of the most important ideas in the statistical theory of matter has been Gibbs's ensemble With the old mechanics the ensemble was a rather strange idea, and it was hard to see where it came from, but now it fits beautifully into the new mechanics, for any actual piece of gas is not merely a single member from among the countless representatives in the ensemble, but is itself the whole ensemble This example suggests a real synthesis of probability with our other reasoning processes, and gives the hope of a true reasoning adapted not to the artificially simplified world of hard outlines of the classical mechanics, but to the real world with its slightly indefinite outlines

The address concludes with a plea for a reform of our education at both school and university, so that probability and statistics should be given a proper share in our mathematical courses At present all the attention is given to things susceptible of exact proof, and none to the things of much more frequent occurrence where inaccuracies, tolerances or fluctuations are also of interest It is not so much that new special courses are needed as that the emphasis should be altered in the ordinary courses of mechanics and kindred subjects The mathematics would not be any more difficult than in the customary courses, but the train of thought is at present unfamiliar, and it would not be hard to remove this unfamiliarity In this way the student would acquire a much juster appreciation of the physical world than can ever be acquired by an exclusive attention to those things which are capable of exact proof

Recent Investigations in the Chemistry of Gold

THE recent advances in our knowledge of the chemistry of gold have for the most part been due to investigations carried out by workers in Great Britain, amongst others, H. Bassett, E G. Cox, F G. Mann, Sir Gilbert Morgan, Sir William Pope, W Wardlaw, and their respective co-workers. This work, together with that of the president of Section B (Chemistry), Prof. C S. Gibson, and his collaborators, which forms the topic of Prof. Gibson's presidential address, has emphasized the similarities and also the striking anomalies existing among the currency metals, copper, silver and gold, the metals of Sub-group 1 *B* of the Periodic

---

* Lord Rayleigh's presidential address, and the addresses of the sectional presidents, are being published as "The Advancement of Science, 1938". (Cambridge: B A. Reception Room London Burlington House.) 3s. 6d.

Classification These anomalies are unexplained but are to some extent correlated with those existing among the transitional metals

Copper silver and gold all exist in the univalent condition but in this state only silver is from a chemical point of view a typical metal since cuprous copper and aurous gold do not form normal salts In their compounds cuprous copper and aurous gold are always co ordinated but whereas cuprous copper may be 2 and 4 covalent aurous gold is always 2 covalent and no compounds are known in which it has a higher co ordination number Argentous silver may be 2 and 4 covalent its co ordination compounds are almost completely analogous with the corresponding cuprous compounds and the four valencies of cuprous copper and argentous silver have a tetrahedral configuration Unlike cupric copper bivalent or argentic silver is chemically not a typical metal since it only forms co ordinated complexes which may be present in electrolytes and non electrolytes When it is 4 covalent argentic silver forms compounds which are analogous and isomorphous with the corresponding cupric compounds and the four valencies of cupric copper and argentic silver have a planar configuration One striking anomaly among these metals is the non existence of bivalent gold In the tervalent or auric condition gold again is chemically not a typical metal and is always 4 covalent Consequently unlike copper and silver gold never assumes the effective atomic number (Sidgwick) of the next inert gas X ray crystallographic examination has demonstrated the planar configuration of the four valencies of tervalent gold and the linear configuration of the two valencies of univalent gold

What may be described as the new chemistry of gold has arisen from the study of the organic derivatives of the metal which were discovered by Sir William Pope and C S Gibson in 1907 and their investigation has been extended by Gibson and his collaborators during the last seven years The organic compounds of gold most readily accessible are colourless crystalline non electrolytes having the general formula $(R_2AuX)_2$ R and X representing univalent hydrocarbon radicals and halogen atoms respectively As shown by the low dipole moment and X ray crystallographic examination the molecule contains the planar ring structure

which is present in many auric and mixed auric aurous compounds

From the bromine derivatives are easily prepared deep red crystalline non electrolytes having the general formula $(RAuBr_2)_2$ These compounds have high dipole moments and contain the same planar heterocyclic ring containing two 4 covalent auric atoms to one of which two hydrocarbon radicals are attached In agreement with their constitution these compounds behave chemically as equimolecular mixtures of the compounds $(R_2AuBr)_2$ and of gold tribromide $(AuB_3)_2$ the latter compound having the same planar heterocyclic ring mentioned above

The remarkable tendency due to co ordination for auric and to a less extent aurous gold to become members of heterocyclic ring systems is further illustrated by the interesting colourless non electrolyte diethylgoldacetylacetone and also by the cyano derivatives obtained by the action of silver cyanide on the first mentioned compounds These cyano compounds are non electrolytes having the general formula $(R_2AuCN)_4$ and the molecule as shown by the low dipole moment and X ray crystallographic investigation (H M Powell and R F Phillips) contains a planar twelve atom ring having four symmetrically situated 4 covalent auric atoms These compounds have the additional interest in that spontaneously or on gentle heating they yield free hydrocarbon radicals The first stage of this decomposition yields a mixed 4 covalent auric and 2 covalent aurous compound $(RAuCN)_4$ the molecule of which again has a twelve atom planar ring structure containing two symmetrically placed auric and two symmetrically placed aurous atoms the latter being 2 covalent

There being no evidence that gold can have higher covalencies than two when it is aurous and four when it is auric precludes the possibility of obtaining optically active gold compounds in which the gold atom is the centre of asymmetry

---

Development and Evolution

THE Theory of Recapitulation which at the opening of this century tended to dominate biological and palæontological thought upon the relationship of development to evolution has in these latter days fallen into disrepute This state of affairs is reflected in recent literature by a diversity of views ranging from complete rejection of the theory to almost unqualified acceptance Prof H H Swinnerton in his presidential address to Section C (Geology) seeks by reference to palæontological evidence to elucidate the causes of this wide diversity of opinion and to harmonize the observations out of which it has arisen

In so far as developmental changes reflect evolutionary changes of the past or foreshadow those which are to come the relationship of development to evolution is either retrospective or prospective Failure to keep these two aspects distinct from one another has been the cause of much of the confusion of thought which exists

The palæontological evidence used in the address is limited to well-authenticated material, made up of numerous specimens carefully collected from known horizons, and is of such a quality that the development of individuals could be worked out with reasonable fullness.

Dealing in the first place with the retrospective aspect of the problem, it is helpful to distinguish between the very early, or embryonic, stages of development and the later, or neanic stages, during which the young gradually assumes the characteristics of the adult A careful comparison of the development with the successive stages of evolution shows that in some cases there is a remarkably close resemblance between the changes passed through in the neanic period and the changes exhibited by the adults of previous generations This proves that recapitulation of evolutionary stages as manifested by adults does actually take place On the other hand, the conditions seen in the embryonic phases exhibit little or no resemblance to any known adult ancestor, but they do resemble very closely the corresponding juvenile stages both of ancestral and of allied forms. This distinction between juvenile and adult recapitulation corresponds with the different bodies of facts observed and emphasized respectively by von Baer and Haeckel, and by their present-day followers

Though the recapitulation of the complete combination of adult characters seems to be confined to the lower forms of life, the limited recapitulation of individual characters is widely spread even in the highest grades of animals

Turning to the prospective aspect of the subject, it should be noted that new characters (cœnogenetic) may appear at an early stage of development Some of these are limited in their occurrence to these stages , others may extend, in subsequent generations, to later or even adult life Where this happens, the recapitulatory record may be seriously vitiated New characters (deuterogenetic) may also appear in the latest stages of development. Such tend, in subsequent generations, to pass back to successively earlier neanic stages, and thus build up a recapitulatory record

In both these cases the rate at which the new characters attain full expression in evolution varies greatly. In some racial stocks it is attained slowly with the passage of a long period of time. In others the successive phases of expression may come quite rapidly. Occasional instances occur in which the rate of expression appears to be so rapid as to suggest simultaneous mutation In such cases a false impression of serial evolutionary change is produced by the progressive elimination of individual types in the order of the phases in the series

In conclusion, it may be suggested that the development of the individual exhibits a body of characters derived from both adult and juvenile stages in the life of its ancestors This provides a framework into which subsequent evolutionary changes may be fitted This fitting is carried out by various processes which may proceed separately, simultaneously, or in sequence in the development of different individuals of allied organisms

Fluctuations in the Abundance of Marine Animals

IN his presidential address to Section D (Zoology), Dr. Stanley Kemp directs attention to the great fluctuations in the abundance of marine animals and to the need for further study of their causes. Normal annual fluctuations, due for the most part to events which occur in the early stages of the animal's life, may be very great : it is not uncommon to find that one year-class of fish is fifty times as abundant as another The evidence at present available, drawn from the incidence of good and bad survival years in a few of the more important European fishes, is that these annual fluctuations are strictly localized—a certain species in a particular place will be affected in one way, while another species in the same place, or the same species in another place, will be affected in a different way

In recent years, it has become increasingly apparent that this is not the only kind of fluctuation to which marine animals are subject. There are others, here called long-period fluctuations, which are superposed upon the annual fluctuations and affect many, or perhaps all, species simultaneously over a wide area

Two illustrations of such long-period fluctuations are given In the Channel waters off Plymouth four separate lines of evidence show that since 1931 great changes have taken place. (1) Beginning with 1931, there has been a steady reduction in the numbers of larval fish in the offshore waters : the larvæ of summer-spawning fish have now on the average been reduced to one fifth of their former abundance and those of spring-spawning fish to one third. (2) A marked change has occurred in the constitution of the herring shoals which form the basis of the winter fishery at Plymouth. Since 1931, the proportion of the younger year classes of fish has been reduced from upwards of 66 per cent to less than 20 per cent : in the last few years the fishery has suffered greatly and it is now virtually abandoned (3) In 1930 (and though exact figures are not available it was evidently much the same in former years) the offshore plankton contained *Sagitta elegans* which is characteristic of mixed Atlantic water and *S setosa* which is characteristic of Channel water in the proportions of 94 6 but since 1932 with a single exception in 1936 these proportions have been reversed (4) The winter maximum of dissolved phosphate has over the same period shown a heavy decrease amounting on the average to about 35 per cent Comparable data from other areas are not available but the failure in recent years of the Donegal herring fishery has been accompanied by a similar change in the constitution of the shoals and may be due to the same causes

The changes in the Plymouth area are due it seems to the lack of influxes of phosphate rich water from the Atlantic Salinity and temperature records show indeed that incursions of Atlantic water have passed up the Channel but the records cannot be correlated with the biological and phosphate data and the great influx of Atlantic water into the North Sea in 1921 is known to have been detrimental to the herring fisheries It thus appears that influxes may be of more than one kind and that only water rich in phosphate or potentially rich because it carries an abundant plankton will benefit the Channel fauna

The second illustration of a long period fluctuation is from northern waters Here there have recently been great changes in the fauna owing to a rise of 1° or 2° C in the temperature of the water and this is due presumably to an increase in the strength of the Atlantic drift By reason of this change many animals have been able to extend the limits of their distribution and in almost every section of the fauna significant movements have been noted profitable cod fisheries have been established at Bear Island and in West Greenland and an unusual abundance of herring has been found on the Murman coast

Long period fluctuations are thus due to a widespread alteration in some hydrographic factor in the environment and though in the two instances given this factor is different—at Plymouth phosphate and in northern waters temperature—it is in the ocean to the west that the changes originate and it is here in the open Atlantic that the reasons must be sought At present our knowledge of the circulation in the North Atlantic is very deficient but with the work now in progress it is to be expected that the main features will shortly be better known To the biologist however it is the irregularities in the system which are of primary importance and it is only by regular and repeated observations carried out over a wide area that the causes of these long period fluctuations can be discovered

In conclusion attention is directed to the need for greater activity in fishery administration throughout the Empire for though there are some notable exceptions it appears that the lessons we have learnt in Great Britain are not generally understood elsewhere In almost every problem in marine biology it is essential to possess a background of fundamental knowledge which can only be obtained by long years of patient study In many parts of the Empire not even a beginning has been made in the acquisition of such knowledge there are vast areas in which no single species of fish can as yet be recognized in all its stages of development while little or nothing is known of such matters as rate of growth spawning periods food migrations and fluctuations in abundance The importance of such information cannot be over estimated for the opportunity of dealing effectively with a fishery problem will almost invariably be lost unless knowledge has been obtained in advance and is ready for application

---

Correlations and Culture A Study in Technique

PROF GRIFFITH TAYLOR S presidential address to Section F (Geography) falls into three divisions In the first the field of cultural geography is considered in the second a technique which has been found invaluable in that subject is discussed and illustrated finally suggestions are made as to the aspects of culture which should be included in a general education The relation of geography to history anthropology sociology and philology is emphasized It is shown that there are common fields of research in which the technique of the physical scientist can be used by the cultural geographer to aid in problems in the humanistic disciplines

The aid geographers can give to historians is illustrated by examples from the Weald and from the blue grass country of Kentucky The characteristic cultural development in both is shown to depend on structure primarily though most historians ignore this important correlation The use of *isopleths* (lines of equal abundance) can be used with profit in an interpretation of the essential features of the Renaissance As an indicator of *trends* and *salient features* they might well be more extensively used by the historian

The geographer s task should be to teach the student to doubt dogmas involving distribution and to make his own deductions from fundamental data In a general education this is a far more valuable function than memorizing economic data which fills so much of geographic teaching to day

One of the main purposes of the address is to show that from the *map* of the distribution of culture-facts, the investigator can deduce the cradle of the various cultures and the order of their evolution This principle, long used by the botanist and biologist, is of great value to the anthropologist, sociologist and philologist The *distributions* of man, of various industries and populations, of languages, etc , belong to the field of the geographer A lengthy study of such distributions leads to views often much at variance with those accepted as orthodox Some examples discussed are the cradle-land of man, the differentiation of the races, the inaccuracy of the terms 'Caucasian' and 'Mongolian', the spread of cultures from Asia into the Pacific, and the probable cradle of civilization In many of these problems the implications of the isopleths have been ignored by most researchers

It is suggested that a new term is needed for groups which are linked by *culture*, but are not racial units. An extension of the use of the word '*cult*' is suggested Thus there is no Jewish *race* in Europe, or French *race* in Canada , but it is logical to talk of a Jewish or French 'cult' Race should denote 'breed', and is purely a *biological* concept The problem of the Jews and of the Aryans is used to illustrate a glaring example of dangerous ignorance on the part of powerful political groups A new technique of approaching linguistic relationships—based on distributions—is discussed. It seems to offer clues as to the relationships between, and the origins of, Aryan, Basque, Altaic, and other linguistic groups Prof Griffith Taylor believes that the Aryan languages originated near the Caspian. He suggests that the isopleths support the view that the Nordic race originally spoke Finn or some allied *non-Aryan* language

Geographers may be classified in three groups *theocratic* (that is, teleological), *environmental* or *possibilist* A belief in environmental control, to which the name "Stop-and-go Determinism" has been given, is favoured It is opposed to the orthodox views of geographic philosophy

A drastic revision of the programme for a general cultural education is required, especially in the Dominions. Educators must abandon the technique of Augustine of Canterbury for that of Aristotle. The latter tried (in a living language) to put the youth of Greece *en rapport* with the vital problems of the day. He did not insist on their spending years trying to learn the long-dead language of Tutankhamen.

It would seem desirable to swing the attention of youth for a generation or two from a study of classics or of the problems of physical science to the more difficult and dangerous problems of social science There is no risk to-day, though there was in the past, in stating that the earth is a globe, revolves around the sun, and is of infinitely small importance in the cosmos But there is grave danger in many circles in stating the truth about Communism, Socialism, Judaism, Nordicism, and many other -isms which conflict with established or dictatorial interests These creeds are cultural facts, which can be more readily understood if tackled in a *graphic* manner It is no quibble to say that they are to-day more vital to the man of culture, that is, with a well-rounded education, than is the well-recognized and valuable culture based on art, music, or classics Thus the geographer whose interests lie not only in the economic but also in the *cultural* field can feel that he is working right on the battle-front in man's progress towards a higher type of civilization

Eighteen ecological diagrams form an essential feature of the address

Scope and Method of Economics

THE object of the presidential address by Mr R F. Harrod to Section F (Economics) on *method* is threefold . (1) An attempt is made to show the kind of knowledge on which the practical recommendations, which economists have been in the habit of giving with a considerable degree of assurance, are grounded. (2) An attempt is made to define precisely the empirical basis of the general laws which constitute traditional economic theory (3) Attention is given to the new ground over which contemporary theory, more tentative and more empirical, is striving to advance.

The recommendations do not issue from a set of 'laws' relating to the causal sequence of events The scientific groundwork of these recommendations is a systematic classification of different kinds of economic activity and a simultaneous conspectus of the system as a whole For example, the condemnation of protection is not based on precise knowledge of the sum of consequences likely to result from it , but when we have made a systematic classification of the purposes of economic effort and grasped the mode of operation of the system of a whole, we see that protection fails to take account of this, implicitly assumes a different working of the system and, save in exceptional circumstances, produces a net residue of frustation.

The economist's criterion of the good as that which is preferred is defined, and it is shown that it may be validly employed whatever the moral or political objectives of the society may be. The economist's criterion is free from moral or political bias, and it has to be employed even if the economist is asked to advise subject to some stated political objective, such as national self-sufficiency

In addition to the system of prescriptions, traditional economics has provided a body of general laws relating to the sequence of events These have been largely deductive, because they spring from a single simple principle, which has an empirical basis, but one derived from an immensely wide human experience, namely the law of demand or the law of diminishing utility This is almost axiomatic and further investigations are unlikely to reinforce the authority it already has By the aid of it and of its corollaries it is possible to derive a theory of supply and demand, by which the effect of specified changes on the course of prices, wages employment, etc may in principle be determined But this law and its corollaries are of very wide generality and consequently are of little use for prediction in any particular circumstances

To have greater predictory power in this field, it would be necessary to be able to state the laws governing the demand for particular commodities, etc in quantitative terms Owing to the plurality of causes it is extremely difficult to derive such laws from the data of observation The quantitative laws would certainly be far more conjectural than the general qualitative results derived from the demand axiom Interesting attempts have been made along these lines But it is probable that the future of quantitative empirical economics lies elsewhere Indeed the success of deductive reasoning up to a certain point has probably caused an excessive concentration of effort on this branch of the subject

The wealth of recommendation which has characterized past economics, may be reconciled with its paucity of predictory power, when it is appreciated that the power does not rest on the few general causal laws which we have but on classificatory and survey work

Contemporary study is seeking new approaches to the establishment of general causal laws, outside the ambit of the traditional laws of demand and supply It is not yet certain whether greater success is likely to be obtained by the hypothetical deductive method, which must depend on suitable data being thrown up by the facts of the working world to take the place of the crucial experiment, or by a more radically empirical method, which seeks by constant study and re classification of the facts to make them speak for themselves and suggest new laws

In one field at least Mr Harrod hopes for a further successful outgrowth of deductive theory. The laws of demand and supply, already referred to, which are sometimes known as static theory', may be compared with the laws of statics relating to bodies at rest It should be possible to develop a system of laws, which by analogy may be called dynamic theory, relating to the behaviour of a system when the fundamental magnitudes, population, capital, etc , are increasing (or decreasing) Mr Harrod suspects that we are on the verge of formulating one or two simple axioms, based on very wide experience and having almost as great an authority as the law of demand in static economics from which a quite complicated set of laws relating to a system in motion may be derived Such an axiom may be that people save a larger amount if they have a larger income Since our society is in fact growing and not stationary the hypotheses which theorists will be disposed to make in this department will be subject to easier verification than those of static theory

This is, however but one out of many possible lines of advance A greater tendency towards the empirical may safely be predicted Empirical work in economics is exceedingly laborious and can only flourish if there is ample endowment for full time research workers The branch of statistical theory of especial use to empirical economists is at present displaying a welcome vitality

Economists should be keenly alive to the findings of workers—sociologists anthropologists, etc on the periphery of their subject But the suggestion recently put forward by one or two eminent persons that economics is in a parlous state requiring salvage by workers in sister subjects is rejected with contempt Of all the social studies economics has been most successful in attaining valid general laws of interest and authority, and it is at the moment in a condition in which an advance over a wide front may reasonably be expected

---

Changing Outlook of Engineering Science

IN Section G (Engineering), seeking a topic of concern to both practising and academic members of his audience, the president, Prof R V Southwell, undertakes a general stocktaking—to view the trend of engineering science regarded both as an art and as a field for study, teaching and research He divides his presidential address into three main sections, dealing (1) with policy in regard to the teaching of engineering science, (2) with policy in regard to engineering research, and (3) with 'foreign policy'—the relation of the engineer to the community , its keynote throughout being that in the changing circumstances of to-day engineers, whether practical or academic, must frame their policies in collaboration, not wait for action to be forced on them by pressure from without

Among changing circumstances are (1) the trend of modern physics (2) the attitude of industry towards the university graduate and (3) the national organization for applied research each has implications which no engineer can afford to neglect In regard to the training of university students which usually occupies five years divided between laboratory and works he urges the desirability of planning for this period as a whole and he suggests that university courses are too often overloaded so that insufficient time is left for those divergent pursuits which do most to develop the personal qualities that industry has come to value Matters appropriate for treatment in the lecture need not necessarily be included in the examination syllabus

Engineering research Prof Southwell believes will continue to be prosecuted in universities not withstanding its increasing demand for specialized knowledge of mathematics physics and chemistry and the increased provision which now exists in Government institutions and in industrial research departments Compared with professional physicists chemists and mathematicians academic engineers have a special point of view and one that is needed Their work will come to approximate more and more to what in the last century was called pure physics schools of engineering will find problems different from those which engaged their energies a generation ago When a problem can be turned over to trained men who will work on it full time it is uneconomic both of brains and of money to pursue it at universities in occasional spells of leisure from the duties of teaching and administration

Under his last heading—public relations—Prof Southwell utters a protest against an implication in much that is written nowadays that because the range of engineering includes guns battleships aeroplanes tanks therefore engineers are to be regarded as a class more than others responsible for the horrors of modern war Wars are not made by engineers but by communities we all have responsibility but as citizens and not as specialists It is vain to talk as though we could have had the benefits of science without its risks and its temptations Either we must choose deliberately impotence as preferable to the power of doing evil or we must accept knowledge for the double edged tool it is vowing to use it wisely

The Orient and Europe

THE distortions of prehistory on the Continent to fit biased and distorted political dogmas and the travesty of the subject broadcast by the B B C a year ago challenge archæologists to justify their membership of an association for the advancement of science by criticizing their hypotheses impartially and objectively in the light of rapidly accumulating concrete facts Prof V Gordon Childe attempts such an examination in his presidential address to Section H (Anthropology)

Prehistory as expounded in Britain rests upon a complex of assumptions collectively constituting the Orientalist position classically formulated by Montelius in Der Orient und Europa published in 1899 His position involved the following assumptions (1) civilization in the Orient is extremely ancient (2) civilization can be diffused (3) elements of civilization were in fact diffused from the Orient to Europe (4) the diffusion of historically dated Oriental types provides a basis for bringing prehistoric Europe within the framework of historical chronology (5) prehistoric European cultures are poorer than contemporary Oriental cultures that is civilization is later in Europe than in the East

In 1899 all these propositions had to be treated as axioms Now systematic excavation in Hither Asia and the Balkans has furnished experimental data by which the foregoing axioms can and must be tested

(1) Excavations at Erech and Ur Tel Asmer and Khafaje Nineveh and Tepe Gawra have dramatically provided concrete proof of the immense antiquity of settled agricultural life in Mesopotamia Estimated dates of the order of 6000 B C for the Tel Halaf phase that is separated from the earliest historical horizons by stupendous accumulations of settlement debris are at least as plausible as similar geological estimates of the age of the North European mesolithic Similarly excavations at Alisar Huyuk Troy and Thermi have vindicated the antiquity of metal using cultures in Anatolia too

(2) The exploration of Anatolia has also provided fresh evidence for cultural connexions with Mesopotamia Taken in conjunction therewith Heurtley s work in Macedonia has established irreversibly the Anatolian origin of the Macedonian Early Bronze Age culture At the same time the Late Neolithic culture that immediately precedes and may partly overlap it proves to be to all intents and purposes identical with that revealed at Vinca and other sites in the south east of the Middle Danube basin Thence culture is well known to be continuous right up to the Rhine whither Mediterranean *Spondylus* shells were imported even in the first neolithic period or Danubian I A cultural continuum can now be traced from the Tigris to the Rhine and affords opportunities for the diffusion assumed in axiom (2)

(3) Oriental prototypes for arbitrary forms of

personal ornament, distinctive of the Early Bronze Age of Central Europe, have been multiplied surprisingly during the last five years. Ingot torques, lockrings and ear-rings with flattened ends, scroll, knot-headed and racquet pins are now all known from Mesopotamia.

(4) In Mesopotamia, however, all these types emerge unexpectedly early. The *terminus post quem* for the beginning of the Central European Bronze Age or Danubian IV is accordingly nearer 2800 than 1800 B.C. Moreover, types distinctive of previous phases of European prehistory have come to light in still earlier contexts in the Orient: battle-axes, for example, such as belong to Danubian III, can be traced back to the Uruk or even the al Ubaid phase in Mesopotamia. Still adhering to a strict application of axiom (4) we can raise the absolute dates attributed to the several phases of the New Stone Age in Europe to meet the estimates of botanists and geologists.

(5) Even so, axiom (5) would remain intact. At the beginning of the Central European Bronze Age about 2800 B.C. we should survey a cultural continuum over which we descend by regular gradations from the great cities of Egypt and Mesopotamia with their fully literate civilization through Anatolian and Ægean townships of illiterate, but metal-using communities to Central European villages where metal was virtually restricted to weapons and ornaments, neolithic hamlets in North Germany and Denmark and pure food-gatherers farther north. At the beginning of the European neolithic period, a couple of millennia earlier, similar relations would hold good: a chalcolithic Assyrian township like Arpachiya would have to be compared to a self-sufficing temporary hamlet of twenty households like Koln Lindenthal, while the boundaries of food-gatherers would be extended southward to the edge of the loess in South and Central Germany.

Even on such a maximal chronology, the orientalist position remains unassailable. But that chronology has been advanced only tentatively to see how archæological deductions fit the hypotheses of other disciplines. It need not be accepted as even plausible unless geologists and botanists become more unanimous and confident.

Eye and Brain as Factors in Visual Perception

IN his presidential address to Section J (Psychology), Dr. R. H. Thouless deals with the implications for the theory of visual perception of the fact that the physiological mechanism of vision is not only the retinal surface but also the whole system which includes retina, optic nerve, visual area of the cortex and, to some extent, other sensory areas of the brain as well.

It was assumed in much of the earlier work in vision (as in that of Helmholtz) that the basic process in vision is the formation of an optical image on the retina and its transmission to the visual centres of the brain by means of the optic nerve. Differences between the sensations transmitted to the brain and the finished perception were attributed to the action of the higher processes of judgment and the influence of past experience. This may be called the 'transmission theory' of vision. Within a certain limited field—that of the sensory physiology of the retina—it proved itself a fruitful guide to research. Modern researches on visual perception have, however, now made it clear that the transmission theory is wrong, and that a wholly different way of approaching the problems of visual perception is necessary if we are not to be led astray.

The modern attack on the transmission theory started from Wertheimer's experiments on the so-called phi movement which is seen when two retinal points are successively stimulated at certain time intervals. This is one of many known examples of the appearance in perception of something which does not exist in the pattern of stimulation.

The same conclusions may be reached by a study of the apparent shape of an inclined object. This apparent shape is not identical with the retinal shape but lies between this and the real shape. Careful consideration of this experiment makes untenable the view that the retinal shape is given as 'sensation', which is modified by a process of 'perceptual judgment'. There is no evidence that the 'sensation' is in any way an ingredient of the experienced shape. Rather the experienced shape appears to be a direct product of both the shape of retinal stimulation and of such perceptual cues as indicate the real shape of the object.

Individual differences are characteristic of the cerebral side of perception. Although the optical system of the eye may not differ much in different individuals, their perceptual responses may be very different. The amount of "phenomenal regression to the 'real' characters of objects" (that is, the extent to which apparent shape, size, and brightness are determined by the real shapes, sizes and brightnesses of objects, irrespective of inclination, distance, and illumination respectively) differs widely from one individual to another. These differences are not generally suspected until they are shown by experiment. The measurements of any one individual, on the other hand, show high self-consistency, even when the period between two measurements is as long as two years.

These differences are not merely of interest to scientific curiosity; they may also have practical consequences. Research has confirmed the prediction (originally made on theoretical grounds) that a high tendency to see objects in their real sizes irrespective of distance should be of advantage to the drivers of motor vehicles The amount of this tendency may be altered by the action of drugs and by the presence of mist and fog, and this change may affect driving. One case has been reported of its change in a neurotic condition

The psychology of vision can no longer be treated as if vision were a function of the eye alone The foundations of a psychology of vision were firmly laid by the work of Helmholtz and his contemporaries, who made a scientific study of the sensory physiology of the eye The most fruitful field of research at present is in those wider problems of visual perception in which the eye and the higher centres co-operate

Physiology of the Plant Cell

PROF W. STILES, in his presidential address to Section K (Botany), defines the general physiology of the plant cell as those vital activities of plants which are manifested by every living cell, and are thus distinguished from those special processes such as photosynthesis, which are restricted to certain specialized organs. These general activities of living matter are respiration and the absorption and excretion of water and dissolved substances

The usually accepted meaning of respiration is that it provides the energy for plant movements and the building up from the products of photosynthesis of substances of higher energy content than these products. Yet as respiration is a constant property of living matter, even when there is no movement and no formation of fresh material it may be questioned whether this current view of respiration is complete. As regards the synthesis of proteins and other complex substances, while there is evidence of the linkage of anabolic processes with the breaking down of carbohydrate, this anabolism only concerns the re-formation of carbohydrates, and no evidence has yet been obtained which sheds any light on the way in which energy released in respiration is transferred to the processes involved in the synthesis of proteins and other substances of higher complexity than those forming the respiratory substrate.

The absorption of water and dissolved substances by plant cells was formerly assumed to be a simple process of diffusion through cell membranes, but during the present century experimental work has shown that while the absorption of non-electrolytes may sometimes take place in this way, the absorption of electrolytes is a much more complex process, for the unequal absorption of the two ions of a salt, and the entrance of the ions of a salt against their own concentration gradients are very general phenomena Theories based on adsorption and interchange of ions have been put forward to account for these observed facts, but while such processes probably operate, it is doubtful whether they afford a complete explanation of the phenomena

The connexion between respiration and the salt relations of tissues was pointed out in 1927, and since then further evidence has been forthcoming which has emphasized the connexion between respiration and the diffusion of salts into plant cells against the concentration gradient. The energy required for the entrance of salt thus is presumably provided by respiration, and theories have been enunciated which regard the absorption of ions as a continuous interchange of the former with the hydrogen and bicarbonate ions continuously produced within the cell as a consequence of respiration While this interchange may be a factor in salt accumulation, there is evidence that the connexion between respiration and accumulation is generally much more indirect, and that the failure of cells to accumulate salt when respiration is lowered through deprivation of the cells of an adequate oxygen supply is related to their generally lowered vitality under this condition.

It is emphasized that salt accumulation, like respiration itself, is a vital process dependent on the protoplasm, while there is some evidence that in the absorption of water by the plant cell, there is in some, though not all, cases an active secretion of water. It is thus clear that a further analysis of the protoplasmic system is necessary for a better understanding of general cell physiology.

The general physiology of the cell is not only of fundamental importance for plant physiology in general, but it is of similar importance for all ecological investigation which is not merely descriptive, while it also impinges on the important fields of mycology and cyto genetics. Cell physiology is the scientific basis of many important plant industries, including those of food preservation and storage

Administration of Public Education

IN his presidential address to Section L (Education) Mr. John Sargent discusses the part which administration, and local administration in particular, ought to play as a medium through which the basic principles of educational science, as revealed either by *a priori* reasoning or as the result of research and experiment, may be translated into action so far as the public system of education is concerned

Attention is directed in the first instance to a change during the last century in the conception of the function of government which has exercised a profound influence on the whole theory and practice of administration This transition is from the idea of the State as essentially a policeman to that of an active promoter and provider of facilities for enabling all citizens to live fuller and happier lives This change of conception as to function is connected with the abandonment in favour of the idea of human progress of the Platonic principle that any social and political order however perfect is bound sooner or later to decay It is clear that both the nature and the aims of an administrative system which is inspired by the belief that it can and should assist individuals along the road to perfectibility will differ fundamentally from those of one which only hopes to postpone inevitable decay

The consequence of regarding the State as some kind of universal provider has been a vast increase in the legislative activities of government and has led in turn to greatly increased devolution of executive functions from the central to the local authority An examination of the capacity of the present local education authorities to cope with their continually increasing burden reveals certain defects, many of which derive from the historical and traditional considerations which have determined the boundaries of English units of local government In brief, the main defects from which local education authorities appear to be suffering are inherent in their large number and in the great variety in their sizes resources and the powers delegated to them , the result being possibilities of overlapping, friction and in many cases of almost intolerable financial strain It is admitted that some of these difficulties are being successfully overcome by co operation but co operation of itself cannot be regarded as an ideal method of administration

A more serious defect arising from the same set of circumstances, lies in the increasing difficulty in securing men and women with the necessary time and intelligence to devote to the business of local government This applies particularly to the unpaid partners in the administrative system The increase in the demands which the business of local government makes on the time of members of authorities, and the parallel increase in similar demands arising from earning a livelihood, are working together to deprive local bodies of the services of persons in the prime of life and actively engaged in industry and commerce The type of disinterested administrator on whom local government was able to rely a generation ago is steadily dying out

It is recognized that any attempt to remedy these defects may involve changes in the traditional boundaries of local government areas and would certainly bring the reformer up against that formidable factor known as local patriotism It is however suggested that fewer authorities with areas and powers more uniform than at present would not only simplify the problems of administration but would also widen the choice so far as personnel is concerned A further suggestion is that consideration might be given to modifying the duties performed respectively by members of the committees and their officials with the view of reducing the present calls on the time of the former Failing this the only alternative would appear to be to attempt to counteract any deterioration in the amateur element by raising the standard of the professional although it is realized that any development along these lines would raise a natural suspicion of undue bureaucratic control and would need adequate safeguards in this respect

A Long-Term Agricultural Policy

PROF R G STAPLETON in his presidential address to Section M (Agriculture) stresses the importance of ley farming in relation to the present day needs of the nation and in general he discusses the bearing of systems of farming on the formulation of a long term agricultural policy He urges that the needs of the nation must be made to govern the activities of the farmer In considering national need it is pointed out that account must be taken of future contingencies as well as of present requirements Thus as well as producing an abundant supply of fresh food our agricultural policy must take heed of war danger, fall in the population and the influences of soil erosion over seas The essential matter is therefore to maintain our acres in a fertile condition, while it is also desirable that we should conduct our farming in such a way as to make possible the maximum of flexibility in commodity production, and to make ourselves altogether less dependent upon imported feeding stuffs

The main features of the arable, permanent grass, nondescript (much permanent grass and a little arable land per farm) and ley systems are outlined, and it is shown that the arable and ley systems are those which accord best with national needs Permanent grass allows of the minimum of flexibility, and does not afford the best means of turning grass as such to the most profitable account By adopting alternate husbandry (ley-farming) it is possible to lime land under the plough, which is always the correct way to apply lime, to maintain the fields of the farm in maximum fertility, and to cash the fertility by means that are not wasteful

Technical details governing the establishment and management of leys for different purposes are considered in some detail, and finally Prof Stapledon considers the action that is necessary in order in the first place that the present condition of our acres may be accurately gauged, and in the second place, to hasten forward the ploughing up of land in permanent grass that is capable of being used to better advantage. He emphasizes the necessity of conducting a proper survey on a uniform basis on the land itself, particular attention being given to the classification of the acreage in permanent grass and in rough grazings

The crucial difficulties standing in the way of ploughing up are lack of facilities and lack of working capital A strong case is made for the extension of credit facilities granted for the explicit purpose of ploughing up and other contingent improvements It is urged, however, that credit facilities should only be given to carefully selected farmers, and then only to those who will contract to work to an agreed plan over a sufficiently long run of years. Apart from credit facilities, much might be achieved by a re-orientation in the financial and other arrangements made between landlords and tenants, and it is urged that ley-farming, if it became more general, would make it possible to adopt a variety of systems of share farming in directions not at present feasible

National Parks and the Preservation of the Flora and Fauna of Great Britain

IN his presidential address to the Conference of Delegates of Corresponding Societies on the use of national parks in Great Britain for the preservation of the fauna, Lord Onslow points out that the term 'national park' covers any natural reserve or open space to which the public have access regardless as to whether it is to be devoted to the preservation of fauna and flora or not, and Lord Onslow discusses methods of utilization of such national parks. The question of the desirability of re-introducing and acclimatizing animals now extinct in Great Britain, such as the reindeer, wild pig, beaver, Irish stoat and lemming, has also to be considered.

Granting the desirability of creating a national park in Great Britain, the first consideration is where to put it. The west coast of Scotland seems to be an ideal spot for such a venture In those counties there exist thousands of acres of deer forest land, which lends itself readily to the creation of a national park Such a forest already contains a considerable number of the animals which it is sought to preserve and it may be hoped that others could be acclimatized there Probably the most attractive animals in a park will be the deer In Great Britain there are three species of deer—red deer, roe deer, fallow deer Whether the latter is actually indigenous or was imported at some remote period has not been decided, but if they are not really wild animals, they exist all over the country in a feral state Other beasts which might well be added to the stock of a national park are the so-called park cattle These, as is well known, exist in a wild state at Lord Tankerville's estate at Chillingham The Chartley and Cadzow herds strongly resemble the Chillingham , a herd of these cattle allowed to exist in a wild state would prove a valuable addition to a national park Then in Scotland there are a few wild goats, which might well be preserved in a national park Perhaps the most interesting animals would be the carnivorous animals Foxes, badgers, stoats and weasels are common enough and exist in Scotland as well as in England and Wales There would be no difficulty about them nor would there be about otters, provided, of course, the park had streams, rivers and burns to provide fish But there are three species which are becoming very scarce indeed, and deserve every effort being made to retain These are the wild cat, the pine marten and the pole cat Perhaps the most difficult beasts to acclimatize in Scotland would be the rarer bats, most of which have only been found in the south of England Rodents are common enough, so their preservation would present no difficulties

Turning from mammals to the birds, one may say that if birds are unmolested, generally speaking they will be present, at least those which are suitable to the district The national park should form a strict bird sanctuary, and if possible part of the park should be near the sea so that sea birds could be encouraged o breed there

As regards finance, forest country in Scotland is now cheaper than it used to be, and it should be possible to acquire the necessary land for the public generally, either under the Government or by means of public subscription A national park would not be so expensive to maintain as a deer forest. In the first place there would be an income coming in, as there is in the National Kruger Park, which makes quite a handsome income. There would have to be a hotel or rest house, and roads and footpaths would have to be made so that people could get about and see the animals.

As regards staff in the park itself, the number employed would probably not be great as in the average deer forest.

The method of management of a national park in Scotland has been ably discussed by Sir Peter Chalmers Mitchell He would put the arrangements for its popular functions in the hands of delegates appointed by Edinburgh, Glasgow, Dundee and Aberdeen, working with delegates appointed by the council or councils of the county or counties in which the park was situated He would add to the governing body of the national park a panel of persons selected for their special knowledge of wild Nature in all its aspects. At least one botanist, one zoologist, one geologist, and two 'field naturalists', one with special knowledge of plants, the other an ornithologist He thinks these might be selected by the principals of the four Scottish Universities, and the presidents of the Royal Society of Edinburgh and of the Highland and Agricultural Society. Moreover, apart from the staff concerned with the general regulation of the park, there should be one warden or ranger selected by the naturalist panel, whose sole duty should be the constant study of wild life in the park and all its fluctuations

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST ALBANS

beneficial earthquake, but one such was reported from Cannes by *The Times* correspondent on July 29 An earthquake shock near the village of Réotier in the Hautes Alpes has removed an obstruction to the water supply which experts for many years have been trying to locate The village fountain, dry for many generations, is now gushing forth water and the acute water shortage is at an end On August 13, a small earth tremor was felt at Pwllheli in Wales, but no damage was done It was probably due to subsidence in underground mine workings.

Scientific Survey of the Cambridge District

WHILE those who are visiting Cambridge for the first time—and indeed many who are re-visiting their *Alma Mater*—will have found the little "Concise Guide to the Town and University of Cambridge", originally written by John Willis Clark, of the utmost value and interest, an even wider audience will have welcomed the book "A Scientific Survey of the Cambridge District" specially prepared for the meeting by the local committee in Cambridge and edited by Dr H C Darby In fifteen chapters, the geology, physiography, climate, biology and history of Cambridge and the Fen District are summarized by specialists, with numerous references to the literature, and with appropriate maps and diagrams In particular, there are, as would be expected, chapters on the drainage of the Fens and on the Breckland The fact that this customary survey of the *venue* of the meeting is now sent out to members a week or so before the meeting opens gives the scientific worker time to learn in advance of the local topics and places likely to be of especial interest to him. The Survey is to be printed as usual in the Annual Report, and additional copies are also on sale (price 2*s*.).

The Darwin Library at Down House

THERE is at present a small collection of books, etc., known as the Darwin Library, at Down House, Downe, Kent, the home of Darwin from 1842 until 1882, which is now in the hands of the British Association. The major part of the existing collection consists of Darwin's own library, which belongs to the professor of botany in Cambridge for the time being, and was generously replaced in Down House by Sir Albert Seward during his tenure of that chair, an action confirmed by his successor, Prof. F. T. Brooks. For the rest, the number of Darwinian books in the possession of the Association is not large, whereas inquiries concerning such books are not infrequently made by visitors and others. The Down House Committee of the Association is endeavouring to collect (*a*) all biographies of Darwin; (*b*) contemporary works on Darwinian theories and kindred subjects; further (*c*) the collection of Darwin's own publications (books and papers) is not complete; and (*d*) the Committee would gladly receive and preserve contemporary reviews of Darwin's works. Those who may be in a position to offer appropriate books or papers are asked, in the first instance, to communicate particulars thereof to the Secretary, British Association, Down House, Downe, Kent, in order that duplication may be avoided.

German Trans-Atlantic Flight

THE four-engined German monoplane *Brandenburg* landed at the Floyd Bennett Field, New York, at 15.54 (New York time) on August 11 after the first successful non-stop flight from Berlin The time taken for the 3,942 miles' flight was a little more than twenty-five hours The machine flew over Newfoundland and the Gulf of St Lawrence, and at noon passed over St. John, New Brunswick She encountered head-winds coming down the coast from Canada, and was flying at a height of 2,000 ft. at 155 miles an hour The return flight was completed successfully on August 14 in just under twenty hours The machine is said to have room for twenty-six passengers, and the flight was designed to show the feasibility of commercial non-stop travel between Germany and America It is an all-metal monoplane with a wing-spread of 108 ft, it carries four 720-h p engines, and has a cruising speed of 196 m p h.

International Geological Congress

AT the seventeenth session of the International Geological Congress held in Moscow in 1937, the Geological Society of London extended an invitation, which was accepted, to hold the eighteenth session of the Congress in London in 1940 The first circular, which has just come to hand, contains preliminary details of the arrangements proposed These include sessional meetings in London on July 31–August 8, 1940, and an attractive programme of excursions—always an important and valuable feature of Congress activity—which will cover most of the important geology of Great Britain and Eire, and will afford the members of the Congress unrivalled opportunity of visiting many of the type-localities under expert guidance. A provisional list of fourteen subjects for discussion at the actual sessional meetings in London is given in the circular Among these we may note magmatic differentiation, the geology of iron ore deposits, the geology of coal seams, the geology of petroleum, the distribution of early vertebrates, earth movements and evolution, the geological results of applied geophysics and the geology of sea and ocean floors The organizing committee, mindful of the fact that this important Congress has not met in Great Britain since 1888, is anxious that the arrangements for the meeting in 1940 shall be as widely known and complete as possible The office and headquarters of the Congress are at the Geological Survey and Museum, Exhibition Road, London, S.W.7, and all communications should be addressed to the general secretaries at that address

Agricultural Research Scholarships and Awards

ON the recommendation of the Agricultural Research Council, the following awards of agricultural research scholarships, studentships for research in animal health and veterinary scholarships have been made by the Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland: Dr. R E. Taylor (King's College, Newcastle-upon-Tyne) a three-year research scholarship in plant pathology, the first year to be spent at Cambridge;

I F Storey (Victoria University, Manchester, and the Imperial College of Science and Technology) a one year research scholarship in plant pathology at the Imperial College D C Thomas (Imperial College of Science and Technology) a two year research scholarship in entomology, the first year to be spent at Cambridge, G W Cooke (University College Nottingham) a three year research scholarship in soil chemistry, the first year to be spent at the Rothamsted Experimental Station, M R F Ashworth (Oriel College, Oxford) a one year research scholarship in soil chemistry at the Macaulay Institute for Soil Research, D J Finney (Clare College, Cambridge) a two year research scholarship in agricultural statistics, the first year to be spent at University College London, A N Worden (Royal Veterinary College Camden Town) a three year studentship in animal health, the first period to be spent at the Lister Institute J A Campbell (Downing College Cambridge) a four year veterinary scholarship at the Royal Veterinary College Camden Town, J L McGirr (University of Glasgow) a four year veterinary scholarship at the Royal Veterinary College, Camden Town The object of these research scholarships and studentships is to train research workers in agricultural science and the science of animal health and in the case of the veterinary scholarships, to enable graduates with honours in science to obtain a veterinary professional qualification, with the view of undertaking research in animal health This year for the first time two veterinary scholarships have been awarded

Announcements

Mr Hugh Lett consulting surgeon to the London Hospital, has been elected president of the Royal College of Surgeons of England.

Mr Sydney A Hurren, head of the Department of Radio Technology at the Northern Polytechnic, has been nominated, for the third year in succession, for election as president of the Institute of Wireless Technology

A new Institute for Atomic Physics has been inaugurated at the Royal Hungarian University for Technical and Economic Sciences, and Prof Z Bay, formerly professor of theoretical physics in the University of Szeged, at present director of the Tungsram Research Laboratory of the United Incandescent Lamp and Electrical Co, has been appointed the first professor of atomic physics

In Nature of August 13, p 287, reference was made to a record crossing of the Atlantic from east to west by the *Queen Mary* On the return voyage, completed on August 14, another record was set up, the *Queen Mary's* time for the distance from the Ambrose Channel lightship to the Bishop Rock was 20 hr 42 min, and her average speed 31 69 knots

The Metro Goldwyn Mayer Corporation is to produce a film of the life of Mme Marie Curie early next year Mr Aldous Huxley will prepare the scenario for the film from an account of Mme Curie's life written by her daughter, Mlle Eve Curie It will be recalled that Mlle Eve Curie was the author of the book entitled Madame Curie" published this year (see Nature of June 18, p 1079) Miss Greta Garbo has agreed to play the part of Mme Curie

A valuable addition to the collection of statuettes of pioneers of the British Empire in the Imperial Institute, South Kensington is the figure of David Livingstone (1813–1873), which has been placed in the Northern Rhodesian Court The cost of the statuette has been defrayed by the Northern Rhodesian Government, to whom a replica is being sent to Livingstone This statuette, like those of Cabot, Van Riebeeck Raffles and Brooke which immediately preceded it in the collection, is a bronze of half life size and the work of Mr Herbert H Cawood, of Sheffield

A Franco Czechoslovak Medical Congress will be held at Prague on September 15–17 Further information can be obtained from the general secretary M A Ravina 254 faubourg Saint Martin Paris

The fifty first Annual Conference of the Sanitary Inspectors Association will be held at Edinburgh on September 5 10 under the presidency of Sir Leonard Hill The subjects for discussion will include shell fish inspection of meat, laboratory control of the milk supply, food and drugs legislation, housing, sanitation, atmospheric pollution, the disposal of trade effluents and a comparison of English and Scottish sanitary practice Further information can be obtained from the Secretary, 19 Grosvenor Place, London, S W 1

The thirteenth Italian Congress of Occupational Diseases will be held at Bari under the presidency of Prof L Ferrannini on September 10–12, when the following subjects, among others, will be discussed occupational pathology of aviation, occupational pathology of athletics, adaptability of the Italian workman to the climate of East Africa, results of the application of compulsory insurance against occupational diseases in the first four years Further information can be obtained from the Secretary, R Clinica Medica, Bari, Italy

The Association for Education in Citizenship is arranging two conferences during October A conference at Birmingham will discuss "The Meaning of Citizenship', and will be held at the University on October 8–10 Mr Anthony Eden, M P, and Sir Norman Angell are among the speakers The second conference will be at Bristol, on "Education for Democracy and the Modern World", on October 14–16 Lord Allen will give the introductory speech on "Democracy—Britain's Need of a Political Religion, and among other speakers are Miss Rathbone, M P, Prof N F Hall, John Bell, Gordon Barry, W McG Eagar and Harold Shearman Further information can be obtained from the Secretary at the Association's offices, 10 Victoria Street, S W 1

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return or to correspond with the writers of rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK S LETTERS APPEAR ON P 360

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Reflection of Atmospherics by the Ionosphere

IN a previous letter to NATURE[1] evidence was given that some atmospherics are reflected at the ionosphere Further oscillographs obtained with an improved technique (see Figs 1 and 2—photographic records on a rapidly moving film of the electric field of atmospherics) have led us to the conclusion that all atmospherics are reflected at the ionosphere The electrical discharge which appears to be lightning in all the observations we have made radiates an electromagnetic disturbance which is propagated as a ground wave and as a series of sky waves which are reflected 1 2 *n* times at an ionized layer at a height *h* km Assuming the velocity of all the waves is that of light and that the sky waves are optically reflected then the intervals of time between the arrival of the ground wave and of the sky waves are given by the expression stated in the previous communication[1]

When an oscillogram enables the times of the arrival of the ground wave and of the first second *n*th sky waves to be determined without ambiguity (Fig 1 is such an oscillogram) the application of this expression is straightforward

In the case of many oscillograms before the identification of the sky waves is possible an assumption needs to be made as to whether the electrical discharge is periodic or aperiodic, and whether the electromagnetic disturbance which it radiates is a damped wave or a single pulse Fig 2 is one of seven almost identical oscillograms observed during a period of 12 minutes We interpret these oscillograms as being due to an oscillating disturbance of five half periods, the first three half oscillations being undamped, and the fourth and fifth damped Further the sky wave once reflected at a height of 95 km arrived 470 µsec after the ground wave and came from a thunderstorm which was known to be at a distance (*d* km) of 70 km The value of the observed maximum electric field strength agrees with this distance This sky wave arrives at an angle of 20° to the vertical and it is emitted at the same angle If the radiator is a vertical lightning flash the intensity of this wave will be proportional to sin 20° and thus the intensity of reflected waves from near sources is small

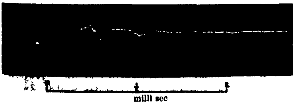

Fig 1

A DAMPED WAVE WITH A SERIES OF REFLECTED WAVES TIME 0115, *d* 190 KM , *h* 88 KM *E* 1 14 *V*/*m*

If the disturbance (on the other hypothesis) is a single pulse then there are sky waves reflected once twice 7 times at a height of 56 km from a source distant 290 km Actually no evidence of lightning at that distance exists and the observed maximum field strength is too large for such a distant storm

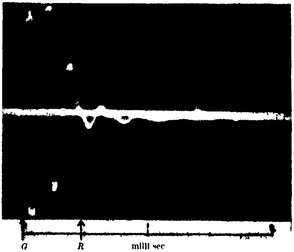

Fig 2

A DAMPED WAVE WITH REFLECTED WAVE ARRIVING 0 47 M SEC AFTER THE GROUND WAVE TIME 1347 *d* 70 KM *h* 95 KM *E* 3 30 *V*/*m*

A characteristic of the observed oscillograms is that all those taken within a short interval of time and probably from the same thunderstorm are closely similar in form This is attributed not to some constant characteristic of the storm itself but to the fact that since a storm is usually of small extent, *d* and *h* would remain approximately constant for the periods of time in question and that this observed fact means that *d* and *h* mainly determine the character of an oscillogram

Date	Time	*r*	*h*	*d*
Feb 20 1937	0115	7	88	190
Feb 27 1937	1104	6	9	200
Feb 20 193	0130	7	88	340
Feb 20 1937	014	6	88	350
Feb 4 1937	1525		6	390
Nov 6 1937	1700		86	4 0

The accompanying table contains the values of *h* and *d* calculated from oscillograms for which a satisfactory identification of the arrival of the sky waves has been made

The equivalent wave length of an atmospheric may be taken as 17 000–40,000 m The values of h in the table mean that if 100 km is the height of the E layer, the conditions of ionization and collision frequency required for the reflection of long waves exist in the upper atmosphere 10–30 km below the boundary of the E layer as determined by the reflection of short waves We have sought for evidence of a D or lower ionized layer, but have found none (If an atmospheric at its source is a single pulse then as stated above, Fig 2 could be interpreted as evidence of the existence of low layers, but the balance of evidence, we think, does not support this interpretation)

An accepted expression for the attenuation of long waves propagated along the ground makes $E\,d$ constant, where E v/m is the field strength at a distance d km from an electromagnetic radiator of constant power $E\,d$ is found to range in our atmospheric observations from 170 to 350 This agrees with evidence previously found by C T R Wilson[2], Munro and Huxley[3], Boswell and Wark[4], that a lightning flash does not vary greatly in its initial electric moment and in its radiating power

In the observations discussed above, the electrical discharge was 70 km or more from the observing instruments

Time and Probability

TIME has recently been the subject of much discussion More than a year ago my colleague, Dr F L Arnot, in connexion with a cosmological theory summarized in NATURE of June 25, directed my attention to the relation between kinematic or atomic time, t, and planetary or pendulum time, τ This may be expressed in the formula

$$\tau = t_0 \log (t/t_0) + t_0,$$

t_0 being a constant of integration representing the present age of the universe at ourselves, reckoned on the t scale" (Milne)

The use of a logarithmic time scale was suggested by de Sitter in 1933, but the further development of such a scale is mainly due to E A Milne Although Milne speaks of t as "probability time ' (1937), this aspect of the time scale does not seem to have attracted much attention, and it is the object of this letter to stress the close relationship between time *as measured* and probability

Boltzmann s formula

$$S - S_0 = k \log (W/W_0),$$

connecting entropy S and "probability ' W, is similar in form to that which connects de Sitter's two varieties of time The entropy formula "corresponds with the fact that entropies are additive and probabilities multiplicative When a system moves into a more probable state, its entropy is increased and its probability is multiplied by a factor (Ubbelhode)

The mathematical resemblance between the time formula and the entropy formula is an indication of the fact that kinematic time t may be interpreted as a probability , and consequently time as measured by an astronomer or physicist is a statistical quantity Illustrations of this statistical interpretation are not difficult to find In using a sand glass we may be able to detect on close examination the motion of individual grains of sand, but we note the passage of time by observing the fall of an assemblage of grains We are dealing with a statistical result and assume that on the average the time taken for the total quantity of sand to pass is the same in successive operations of the hour glass In the water clock, or clepsydra, the same principle is applicable, but the moving particles are of smaller dimensions When a rigid body, a pendulum or rotating planet, is used for the measurement of time, we are again concerned, from the point of view of atomic or molecular theory, with a statistical result

Eddington s picturesque description of entropy as ' time s arrow need not be taken too seriously In Philosophy and the Physicists , Stebbing has taken objection to the view that entropy may be regarded as the signpost of time The experimenter must be aware of the order of his observations before he can draw conclusions from them In the majority of his experiments, he is dealing with statistical results The familiar phrase the tide of time is in some measure suggestive of a statistical interpretation of time

Cosmological and Atomic Constants

IN view of some recent contributions[1] it may be considered not altogether useless to point out a few more relations (or 'coincidences') between some fundamental magnitudes that occur in astrophysical theory and very large dimensionless numbers that can be constructed from atomic constants and the constant of universal gravitation G If γ_1 and γ_2 represent the large numbers constructed from (e, c, m_H, G) and ($\hbar$, c, m_H, G) respectively, then

$$\gamma_1 = \frac{e^2}{m_H{}^2 G} \sim 1\ 23 \times 10^{36},\ \gamma_2 = \frac{\hbar c}{m_H{}^2 G} \sim 1\ 87 \times 10^{38} \quad (1)$$

$$\text{and } \alpha \equiv \frac{\gamma_2}{\gamma_1} = \frac{\hbar c}{e^2} \sim 137,$$

where $\hbar$ is Planck's constant (multiplied by $1/2\pi$), c the velocity of light, e the electron charge, m_H the mass of the proton, and m the mass of the electron

It is known[2] that the usual theory of the white dwarf stars, when combined with the theory of pressure ionization predicts a maximum radius for a cold body, that is, a stellar mass composed of matter degenerate in the sense of Fermi-Dirac statistics Let $R_{\text{max.}}$ denote this maximum value of the radius and M_0 the corresponding mass, then it is interesting to note that the large (astrophysical) dimensionless numbers M_0/M_H and $R_{\max}/\left(\frac{\hbar}{mc}\right)$ which we can construct from the fundamental magnitudes M_0 and $R_{\max}$ are very simply related to γ_1 and γ_2

In fact, apart from numerical factors of order not far different from unity, the theoretical expressions for $R_{\text{max.}}$ and M_0 show that

$$\frac{M_0}{M_H} \simeq \gamma_1^{3/2} \sim 10^{-2} \bigcirc, \frac{R_{\text{max}}}{\frac{\hbar}{mc}} \simeq \alpha^{1/2} \gamma_2^{1/2} \sim 0\,1\, R_0, \qquad (2)$$

where $\bigcirc$ is the mass of the sun, R_0 its radius Further, if M_1 denotes the (Chandrasekhar–Stoner)[3] upper-limit to the mass of the completely degenerate configuration, then again apart from numerical factors

$$M_1/M_H \simeq \gamma_2^{3/2}, \quad . \quad . \quad . \quad . \qquad (3)$$

a 'coincidence' which has already been pointed out by Chandrasekhar. It is interesting to see that

$$\frac{M_0}{M_1} \simeq \left(\frac{\gamma_1}{\gamma_2}\right)^{3/2} \div \alpha^{3/2} \quad . \quad . \quad . \quad . \quad . \quad . \qquad (4)$$

It will be observed, as has been noted by Chandrasekhar (though in a slightly different form) that if the power of γ_2 be taken not as $\frac{3}{2}$ but $\frac{3}{2} + \frac{1}{4}$ and $\frac{3}{2} + \frac{1}{2}$, it gives (roughly) the order of the number of particles in a galaxy and the 'universe' respectively.

It may be further pointed out that if γ_2 in (2) be similarly given powers of $\frac{1}{2}$, $\frac{1}{2} + \frac{1}{4}$ and $\frac{1}{2} + \frac{1}{2}$, we obtain the order of the maximum radius for a *cold* body (roughly) the radius of a galaxy and the Universe respectively.

The time-dependence of γ_1 and γ_2 according to the ideas of Dirac and Milne will be reflected in a corresponding time-dependence of M_0 and R_{max}[2] and other astrophysical magnitudes.

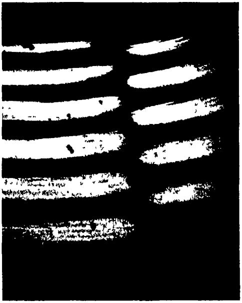
Interference Patterns with Liesegang Rings

ANYONE who is experimentally familiar with the production of Liesegang rings in gelatine films and other allied phenomena might well feel tempted to believe that such periodical precipitates are to be regarded as wave-patterns. Indeed, several workers in the field appear to have felt that the analogy between the Liesegang phenomenon and a wave-effect is not merely superficial, and have sought for more positive evidence in support of it. Leduc and others, for example, claimed that Huygens' well-known optical principle gives an explanation of the form of the rings observed when a precipitating agent diffuses through a narrow aperture in an obstacle cutting across the film More recently, some Russian workers[1] have gone further and suggested that the periodic precipitation itself is to be explained in terms of the de Broglie waves associated with the movement of the precipitating agent, and claim to have been able to measure the 'refractive index' of such waves in passing across a boundary separating regions of different concentration of the gelatine.

The distinguishing character of a true wave is the existence of phase relationships, and connected therewith, the possibility of interference effects. In the course of some studies made by us, we have observed some phenomena with Liesegang precipitates which are unmistakably in the nature of interference effects. To make the significance of our results clear, it is necessary to make here a remark regarding the structure of an interference field When two wave trains crossing at an angle are superposed, we have, of course, regions of maximum and minimum disturbance If the minimum disturbance is actually zero along a given line, the wave fronts on either side of it show a difference of phase of half a wave. This is an exceedingly characteristic interference effect and can easily be recognized in ripple photographs

When on a gelatine film containing a very small concentration of sodium chloride a drop of silver nitrate is placed, the Liesegang pattern consisting of thousands of closely spaced rings of silver chloride precipitate may be observed. On an examination of the precipitate, it is often seen that the patterns are not of uniform intensity everywhere, but show lines of minimum and maximum disturbance, and the effects observed are closely analogous in some cases to beats, and in other cases to interferences of the individual waves In the latter case, the difference of phase of half a wave-length on either side of a line of zero disturbance is invariably to be observed.



INTERFERENCE PHENOMENON OF SILVER CHROMATE RINGS IN GELATIN.

Even more striking are the interferences which we have observed in suitable circumstances with silver chromate rings in gelatine. In this case, the pattern really consists of a great number of fine rings, the intensity of which varies in such manner that they form a succession of widely spaced groups. Not only the individual waves, but also the groups, show interference phenomena with the characteristic discontinuity of phase of the group on either side of a line of zero disturbance The accompanying photograph shows this in a striking way.

Some New Anthocyanin Types

A WIDE survey of anthocyanins occurring in the angiosperms (and a few gymnosperms) has revealed the overwhelming predominance of pigments based on pelargonidin, cyanidin and delphinidin and methyl ethers of the last two The only exceptional cases are the nitrogenous anthocyanins typified by the beet colouring matter, gesnerin from flowers of *Gesnera fulgens* which is the sole representative of the flavylium class related to flavones rather than to flavonols, and certain yellow pigments such as those of *Papaver nudicaule* and *Celosia cristata aurea*

The colouring matter of the yellow Iceland poppy has been isolated, it is nitrogenous, and will be described elsewhere That of the yellow *Cristata* resembles it in some respects but differs in others, it is doubtful whether either is a flavylium salt

We have recently found that the red colour of certain *young* fern fronds (the coloration soon disappears) is due to entirely new anthocyanins in some cases, *in others the familiar pigments have been* identified

Among the Pteridophyta examined we may mention *Davallia divaricata* as containing mixed pelargonidin and cyanidin dimonosides in an acylated form This shows that normal anthocyanins may occur in the cryptogams

The new types occur in *Osmunda regalis* var *Hillii*, and *O palustris Didymochloena truncatula, Pteris aspericaulis, Blechnum brasiliense Dryopteris varia Adiantum Vietchianum* and *Polypodium rhodoleuron*

The anthocyanins include monoglycosides and diglycosides, the anthocyanidins, of which at least three kinds have been recognized, are not identical with any known polyhydroxyflavylium salts They resemble however, 6 hydroxypelargonidin and 6 hydroxycyanidin

By-products in Aromatic Nitration

IT was known fifty years ago that hydroxy by products arise in small quantities in the nitration of benzene and toluene, and their significance was discussed by Armstrong and Rossiter in 1891 Since that time little has been added to the subject apart from a number of observations of the increased production of such by products in the presence of mercuric salts

We have now found that, in the nitration of aromatic compounds with *meta* directive groups, hydroxy by products are formed in considerable quantity in the nitration of nitrobenzene, for example, styphnic acid is produced in amounts varying from 0 5 to 6 5 per cent according to the conditions

The process appears to involve the direct introduction of a hydroxyl group in the *meta* position, followed by complete tri nitration (directed by the hydroxyl group) The resulting substance then either appears as such—for example, hexanitro 3 3′ dihydroxybenzophenone formed in the nitration of benzophenone or the original directive group, now subject to the influence of three nitro groups is displaced by hydroxyl, and styphnic acid is isolated—as for example in nitrating nitrobenzene, phenyl methyl sulphone or diphenyl sulphone

Quantitative Measurement of Vitamin B_1 and its Phosphoric Esters and their Synthesis in Animal Tissues

RECENTLY, in NATURE, Westenbrink and Goudsmit[1] described estimations of the vitamin B_1 and cocarboxylase content of animal tissues based upon the observation that thiochrome phospho esters do not pass into a butyl alcohol layer[2]

In results described to the Biochemical Society on May 5, 1938[3], and embodied in a paper just sent to press, we have given estimations of these two forms of vitamin B_1 by different methods in rat and pigeon tissues Our methods of estimation are based upon the use of yeast enzymes, and are in some sense complementary to those of the above authors, because the cocarboxylase as estimated by us can only be the diphospho ester, whereas *in their method it* is possible that the mono ester is also included, on the other hand our method does not distinguish between vitamin B_1 and its *mono*phospho ester It is interesting that our main conclusion was substantially the same, that there is more cocarboxylase than vitamin B_1 in most tissues, though muscle in our experiments contains relatively more of the latter We also found that vitamin B_1 injected into the avitaminous animals is rapidly taken up by the liver, giving an accumulation of both forms of the vitamin, differing from them, however, slightly increased amounts of free aneurin were found in brain and muscle soon after injection It will be interesting if the points of difference are due to the presence of the mono phospho ester

We may add that (as already mentioned to the Biochemical Society) liver slices produce cocarboxylase from vitamin B_1 Liver slices or 'brei may convert 25–30 per cent of the vitamin into cocarboxylase in 30 minutes at 38° The synthetic reaction has a markedly alkaline *p*H optimum (about 8 5), it is inhibited by iodoacetic acid (0 0009 mol) and little affected by fluoride (0 04 mol) or by addition of phosphoglyceric acid and adenylpyrophosphate, whether separately or together Other tissues show either a very limited activity (brain, muscle) or none at all (intestinal mucosa), kidney tissue has not so far been investigated by us We have recently found that the synthetic reaction can also be obtained with liver extracts, this is being further investigated

Season and Rate of Conception

THE many difficulties of studying the effect of season upon birth rate (or conception rate) have been listed in Huntington's recent book Season of Birth Factors such as birth control, a popular season for marriages, the return of males at holiday seasons, etc , all tend to obscure the actual relationship Because conception—but not the number of young resulting from it—can be influenced in these ways, it seemed wise to find the seasonal effect by studying the ratio of multiple conceptions to single conceptions (It is assumed that the seasonal factors affecting single conceptions act in the same way, though to a greater extent, in affecting multiple-conceptions) Suitable data are difficult to find , the best I have been able to obtain are those from medical officers of health in the large cities, and the accompanying table summarizes those very kindly extracted for me by the Medical Officer of Health for Liverpool They cover the two years 1935–1937 (To medical officers of health, births must be notified within thirty-six hours ; the Registrar General's figures are not so reliable, as births may be notified up to forty two days)

THE NUMBER OF MULTIPLE CONCEPTIONS PER 1 000 SINGLE CONCEPTIONS AT DIFFERENT SEASONS OF THE YEAR

Month of conception	No of single conceptions*	No of multiple conceptions*	Multiple conceptions per 1 000 single conceptions	Month of birth

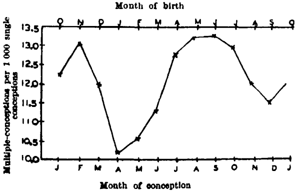
Dec	3024 50	34 75	11 49	Sept

* Standardized to month of 31 days and smoothed by formula $\frac{a+2b+c}{4}$

The numbers of single conceptions by month of the year do show a seasonal trend but are subject to the influences mentioned above

The ratio of multiple conceptions to single conceptions (1 pair of twins or triplets = 1 multiple conception) shows two distinct peaks, as illustrated by the accompanying graph, one around mid February and another around the middle of August to September. It is suggested that this curve shows the seasonal effect uninfluenced by artificial control and that the increasing hours of daylight to the first peak and decreasing hours to the second offer the best explanation of the phenomenon An increase in temperature and improvement in environmental conditions (summer holidays, etc) could not explain the rise in January and February although they might explain the more extended effect in the second peak Conversely, the cumulative effects of a debilitating winter environment finally overcoming the light effect at the beginning of the year might explain the low level in April



It is hoped to study the question further with more data in Great Britain and with data from other countries in different latitudes

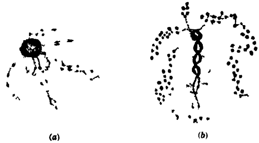
Development of the Inert Regions of the Salivary Gland Chromosomes of *Drosophila*

THE present communication is closely connected with my letter entitled Development of the Giant Salivary Gland Nuclei of Drosophila"[1]

To the genetic conception of inert and active regions of the chromosomes corresponds the morphological conception of the heterochromatin and euchromatin[2] The heterochromatin regions are situated in the metaphase chromosomes near the spindle fibre attachment point, that is on the proximal ends of the rod like chromosomes and on both sides of the spindle attachment constriction in double armed chromosomes

The heterochromatin regions come closely into contact in the telophase, and according to Heitz[3] they fuse and form the chromocentre of the resting nuclei (Fig 1*a*) The study of the development of the salivary gland nuclei of *D funebris* has shown an opposite process, namely, the chromocentre is transformed into the heterochromatin region of the *X* chromosome



(*a*) (*b*)

Fig 1

(*a*) NUCLEUS OF FAT BODY CELL OF AN IMAGO OF *D funebris* (*b*) SALIVARY GLAND NUCLEUS OF A LARVA OF *D funebris* ABOUT 2 5 MM LONG (×3,200)

The dimensions of the chromocentre of the resting nuclei depend on the total quantity of heterochromatin of all the chromosomes In *D funebris* the chromocentre is very large (Fig 1*a*) and is often divided into parts In the salivary gland nuclei of small larvæ (2 5 mm long) the chromocentre lengthens and divides lengthwise into chromomeres arranged in two rows On the chromocentre, however, two chromosomes twisted together with symmetrically arranged chromomeres are clearly seen in Fig 1*b* The distal end of this changed chromocentre passes over into the euchromatin region of the *X* chromosome The heterochromatin and euchromatin regions differ profoundly according to the intensity of Feulgen s reaction The proximal ends of the autosomes continue to unite with the heterochromatin region of the *X* chromosome in the same way as they united formerly with the chromocentre

When the chromosome bands begin to form the heterochromatin region extends still more and the small number of chromomeres of early stages disintegrate lengthwise into a greater number When the genonemata become double the number of chromomeres in the row is also doubled in both euchromatin and heterochromatin chromosome regions Thus a typical picture of the inert region of the *X* chromosome of *D funebris* in the salivary gland nuclei of large larvæ is obtained

When the bands in the salivary gland chromosomes of *D melanogaster* are formed the round chromocentre of a resting nucleus divides into parts belonging to separate chromosomes These chromosome parts divide into chromomeres later on

In *D repleta* the double armed *X* chromosome is represented only by one banded chromosome in the salivary gland nuclei This can be explained only by the fact that the second inert arm forms the chromocentre which in the large salivary gland nuclei does not differ externally from the chromocentre of the resting nuclei In other words, this arm retains the same compact condition as in the resting nucleus

In the large salivary gland nuclei of *D virilis* and *D robusta* the chromocentre of a resting nucleus is retained as in *D repleta* but is decreased in dimensions This can be explained by the fact that in young larvæ small parts separate from the chromocentre and disintegrate into chromomeres Later on the number of chromomeres doubles exactly in the *same way as in the euchromatin chromosome regions* The remaining part of the chromocentre represents a fusion of small parts of heterochromatin, proximal ends of all the chromosomes in *D robusta* and in *D virilis* all the heterochromatin of chromosome III in addition

The differences of the structure of the point of union of the proximal ends of all the chromosomes in the salivary gland nuclei of large larvæ of different species of *Drosophila* can thus be explained whether the whole or a section of the chromocentre of a resting nuclei is transformed into the inert chromosome regions, that is obtains a chromomere structure

The thread leading from the chromocentre to the nucleus is formed during the transition from telophase to the resting nucleus Its nature has so far not been made clear

Chromosome Numbers in *Cimex*

A SUB SPECIES of *Cimex*, phenotypically intermediate between *C lectularius* and *C columbarius* and obtained from laboratory white rats has been found to comprise two forms differing in the number of chromosomes In most cases the haploid number of autosomes is twenty four but in occasional specimens it is sixteen No variation in phenotype, correlated with this change in number, has been observed, nor is the normal course of meiosis affected

This suggests that eight autosomes in this sub species either represent a duplicate set the functions of which can be performed by the remainder of the complement or are genetically inert

All *C lectularius* material so far examined has yielded a haploid autosome count of twenty Since these three karyotypes form a series having chromosome numbers which are multiples of four there is reason to suppose that (*a*) the genus is polyploid in origin, (*b*) the stem number in *Cimex* is four and not six as was suggested by Slack[1] and Vandel[2] for the Heteroptera

Time Sequence of Crossing-Over

MATHER[1] has answered the challenge of Charles[2] regarding the time sequence of crossing over Like Charles, I feel sceptical of Mather s evidence[3] that crossing over begins near the centromere

Mather suggests that the experiments on the effect of age, temperature and inversions in *Drosophila* show the differential effect between the centromere and the ends of the chromosome to be expected on his hypothesis Before he can use this evidence as a support for his hypothesis he must first show that the genetically unsplit region near the centromere behaves similarly to the ends of the chromosomes in all other respects than crossing over It is perfectly reasonable to suppose that the genetically unsplit region and its neighbourhood react quite differently to external influences Indeed there is much evidence for this but it is not necessary to assume as Mather does, that the observed changes in linkage are due to the fact that the first formed chiasma is proximal to the centromere If for example an increase in temperature influences the distance at which the *chromosome is genetically split at the time of crossing* over, the changes in linkage values will be observed no matter where crossing over started on the chromosome

The precocious splitting in unpaired parts of trivalent or univalent chromosomes provides more factual evidence than that adduced by Mather The papers by Charles, Schweitzer and Mather are most useful in suggesting novel modes of attack, but indicate the dangers of jumping to conclusions, however reasonable which are derived from the cytological or statistical methods at present favoured by many

Until the mechanics of chromosome pairing are understood, it is difficult to utilize the data of pairing in structurally changed forms in the way Mather has done A juxtaposition of the centromeres at early meiotic prophase as seen in salivary glands would account for the behaviour of the heterozygote of the Delta 49 inversion, but without factual evidence such a suggestion is as useless as Mather's It is possible that Mather is correct in his assumption regarding this theory, but more genetical evidence is required before acceptance is possible

'Bridlington Crag' Shells

Many years ago, Mr W Headley, a relative of the late G W. Lamplugh, had an extensive collection of shells from the so called 'Bridlington Crag' exposed during excavations near the shore at Bridlington This contained a number of 'types' which had been referred to in the *Quarterly Journal of the Geological Society of London*, vol 47, 1891 We have been endeavouring to trace these, but have recently ascertained that, before he died, Mr Headley sold some of his collections, and possibly these were among them Inquiry has been made as to their whereabouts in the most likely channels, but without result Is it possible any readers of Nature can help us, as it is desirable to know where they can be consulted ?

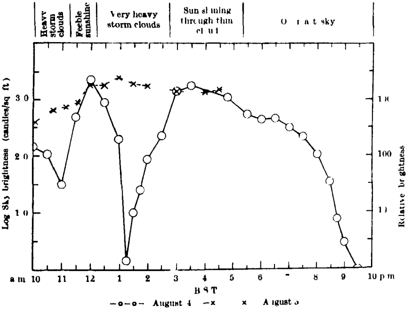
Sky Darkening Associated with a Severe Thunderstorm

It may be of interest to record some observations made here of the abnormal degree of sky darkening associated with a very severe thunderstorm which affected a large area of south-west England during the morning and early afternoon of Thursday, August 4, 1938



Observations of the brightness of the sky in the zenith were made by me at frequent intervals during the day with a Weston photo-electric (barrier layer) photometer calibrated directly in brightness units, namely, candles per sq foot A neutral (silver deposit) screen of known transmission factor, used in conjunction with the photometer, enabled measures to be obtained of brightness values which lay outside the scale range of the instrument The photometer was exposed in a horizontal position, the sky radiation received being restricted to a cone of solid angle 60°. The complete series of observations is shown graphically in the accompanying figure, the logarithm of the photometer reading being plotted in order to form a convenient ordinate scale A scale of relative brightness has been added to facilitate interpretation of the graph The comparison (broken) curve is that for the following day, August 5, when no precipitation took place during the period of observation, and the sky was continuously overcast Notes of sky conditions along the upper margin of the figure refer to the day of the storm

It will be seen that, during the period of most intense storm activity, a wide and rapid fluctuation of sky illumination occurred Within a period of one hour, from 12 15 p m to 1 15 p m B S T, the brightness value had fallen from 1500 to 1 5 candles/sq ft It would appear that the latter value, the absolute minimum recorded, is an unusual one seldom associated with storm centres developing in these latitudes The abnormally low brightness of the sky is here indicative of a great vertical extent of the cumulo nimbus cloud layer passing over the observer

An equally striking return of skylight ensued as the storm centre moved away in a north west direction Half an hour after the minimum brightness had been recorded a reading of the photometer indicated a ten fold increase in the illumination, and by 2 30 p m B S T the reading had risen to 225 candles/sq ft the storm clouds being then in process of dispersion Thereafter, with a broken sky veiled in alto cumulus and cirro stratus cloud through which the sun shone feebly, the sky brightness approached a more normal level, a value of 1770 candles/sq ft being recorded at 3 30 p m B S T By reference to the figure it will be seen that at 9 15 p m B S T the normal twilight illumination had fallen to the same value of sky brightness as that observed soon after midday, when the most severe phase of the thunderstorm was being experienced

Dillenian Correspondence

In the notice in Nature of July 2, p 18 of the recent acquisition by the Department of Botany, British Museum, of a large number of drawings by Dillenius and some manuscript, a 'feeler' was put out about the possibility of Dillenius's correspondence similarly coming to light

A day or two later, having occasion to consult Dawson Turner s correspondence of Richard Richardson (1835) -a book much less well known than it deserves to be as it contains much information about eighteenth century botanists—I happened across a footnote in the preface (p ix) since, so far as my inquiries go, this seems to have been overlooked by botanists, it seems worth reprinting

'As, in speaking of the correspondence of Sloane and Sherard, I have mentioned the advantage derived to science from the preservation of such letters, so is it right here to notice an unfortunate event of an opposite tendency, whereby it is impossible to say how much we may have lost The event I allude to is the destruction of Dr Sibthorpe s papers, and, I fear, with them, of all those of the older Botanists belonging to the Oxford Garden This, I the rather notice, not only inasmuch as my so doing may serve as a warning, and because the papers in question were in a measure connected with the present volume but as affording an opportunity of clearing the late Dr Williams from blame in the transaction Mr Upcott had mentioned to me, that he had found upon a druggist s counter at Oxford, sundry letters written by Sibthorpe Dillenius, &c and that the druggist had told him they were a portion of a large quantity he had bought from the Botanic Garden , so large that, after keeping what he wanted for himself, sufficient remained to be worth sending to a neighbouring paper mill Dr Daubeny the present Professor of Botany, to whom I mentioned the circumstance was kind enough to investigate it, and to write to me as follows The fact is, that, on the pulling down by the street commissioners of the house belonging to the Professor of Botany, various papers, for which there could not have been room in the only apartments that then remained attached to the garden (the present lecture room,) were removed to Dr Sibthorpe's private dwelling house, which, on the death of the son and afterwards of the father, fell into the hands of Lady Sewell, daughter of the latter, and sister of the author of the *Flora Græca* On the decease of that lady some years back, the effects were sold, and amongst them was the lump of old papers you mentioned With regard to the share which my predecessor, Dr Williams, had in the transaction all the information I have been able to obtain, leads me to conclude that at the time of the sale he was not aware of such papers being put up to auction On the contrary, I have been told that, he had several times made application to the Sibthorpe family for the restitution of the books or papers belonging to the garden in their possession , but that they never attended to his request , and that at the sale he actually purchased and restored to the garden several volumes that he had reason to consider as public property

July 25

Points from Foregoing Letters

OBSERVATIONS are recorded by Prof Laby and his colleagues which lead them to conclude that *all* atmospherics are reflected at the ionosphere and lightning is an oscillatory discharge (In a previous letter to NATURE evidence was given that *some* atmospherics are so reflected) In principle, this means it is possible to infer from one oscillogram of an atmospheric the height of the ionosphere, and the distance of the lightning from which the atmospheric was radiated The latter is of considerable practical importance to meteorology and aviation

A logarithmic time scale was suggested by de Sitter in 1933, and Milne has used two time scales connected by a logarithmic expression Prof H S Allen points out the similarity between this expression and Boltzmann s formula connecting entropy and probability Atomic time may be interpreted as a probability, and consequently time as measured by an astronomer or physicist may be regarded as a statistical quantity

Further numerical relations between fundamental atomic constants and the universal gravitation constant, which coincide roughly with values ascribed to the number of particles in, and radii of, the galaxy and the universe are pointed out by Dr D S Kothari

Sir C V Raman and K Subbaramiah submit photographs of Liesegang rings of silver chromate, showing an interference pattern with characteristic difference of phase of half a wave length on either side of a line of zero disturbance

A chemical investigation of a nitrogenous anthocyanin pigment obtained from the yellow Iceland poppy, and of other new anthocyanin pigments from certain young fern fronds and other plants, is announced by J R Price, V C Sturgess, Prof R Robinson and G M Robinson

Prof G M Bennett and Dr P V Youle find that in the nitration of nitrobenzene and other aromatic compounds with a meta directive group, hydroxy acids (for example, styphnic acid) are produced in appreciable quantities

Dr S Ochoa and Prof R A Peters have determined by an enzymic method the cocarboxylase and vitamin B_1 (or monophosphate) content of animal tissues and obtained independently similar results to those of Westenbrink and Goudsmit, except for muscle and brain , it is suggested that the differences may lie in the methods Liver (both slices and extracts) synthesizes cocarboxylase from vitamin B_1 *in vitro*

A graph showing the ratio of multiple conceptions (twins and triplets) per 1,000 of single conceptions at different seasons of the year is submitted by J Edwards It shows a peak around mid February and another around the middle of August to September

Diagrams of cell nuclei from the fruit fly, ***Drosophila funebris***, showing the distal end of the chromocentre passing over into the 'euchromatin region of the *X* chromosome, are submitted by S Frolova to illustrate the development of inert regions in the chromosome

From the consideration of autosomes as distinct from sex chromosomes, Dr H D Slack finds difference in chromosome numbers in *Cimex*, which suggests that polyploidy has played a part in the evolution of the present karyotypes

Dr F W Sansome considers that more genetical evidence is needed before Mather's view that crossing-over begins near the centromere can be accepted

Observations by D R Barber made with a photoelectric photometer of the brightness of the zenith sky throughout the progress of the storm over south west England on August 4 indicate that, during the most severe phase, the sky light was reduced to less than one thousandth part of that normally received from an overcast sky at summer noon

Research Items

Christmas and New Year Among Serbian Gypsies

Dr. Alexander Petrovic concludes his study of feast days among Serbian gypsies with an account of Christmas, New Year and Easter observances (*J. Gypsy Lore Soc.*, **17**, Ser. 3, 1938). Gypsies have many Christmas customs borrowed from the Serbs. These are rites to secure them a favourable year as regards stealing, while on New Year's Day the most important rites are connected with money—the world at large must be informed how much money each gypsy family possesses. If they have money on that day, they will assuredly have it throughout the year. Among the Serbs, Christmas as a holy day occupies a special place. It is a time of joy and merriment, and, as it were, the beginning of a new life. There must be no quarrels, and all kinds of work must be begun to bring good luck. On Christmas Eve, straw is brought into the house and corn is threshed symbolically. The head of the house stands in the centre with a whip and slashes at the women, who represent horses, as they run round him in a circle. Among the gypsies of Kragujevac straw is purchased in conformity with the Serbian custom that straw must be brought into the house, but a few straws must be stolen to accord with gypsy custom. The women go from house to house among the peasants on Christmas Eve and try to steal something from each for their bags, so that their bags may be full throughout the year. At Kopljari, though the peasants observe no special rites on New Year's Eve, the gypsies repeat nearly all the Serbian customs of Christmas Eve. Branches of the Christmas log are used to stir the fire and branches of cornel are brought into the house for the sake of the health of everybody. These used to be decorated with coins, but now banknotes are used, while on New Year's morning all the money in the house is thrown into a blanket spread in the middle of the floor after being poured over branches of the Christmas log. These branches are thrown into a rapid stream to induce money to flow into the house. Among 'Turkish' and Mohammedan gypsies the ceremonial dismemberment and disposal of a turkey play a great part.

Typhoid-Paratyphoid Vaccination in the British Army

Lieut.-Colonel J. S. K. Boyd read a paper at the recent meeting of the British Medical Association on recent advances in the preparation of prophylactic typhoid-paratyphoid vaccines in the British Army (*Brit. Med. J.*, August 6, p. 307). The original vaccine used in the Army was prepared from a strain of the typhoid bacillus of low virulence. Later, doubts were expressed regarding the suitability of this typhoid strain for vaccine preparation, and several researches suggested that the degree of protection afforded by a typhoid vaccine corresponded directly with the virulence of the typhoid strain employed. It was also shown that the reaction caused by vaccines of virulent strains was no more severe than that given by the old strain. A mixed vaccine of *Bact. typhosum*, and *Bact. paratyphosum*, *A* and *B*, of proved and tested virulence, was, therefore, brought into general use in the Army in 1933. The results of this measure can best be studied by following the incidence of typhoid fever in the British Army in India. The curve of incidence showed an upward trend until 1919. The vaccine used was then changed to embody 50 per cent of a 'smooth' variant of considerable virulence. From 1929 a decline in incidence occurred, which was sharply accentuated in 1934 following the introduction of the new vaccine. There was no corresponding decline in the incidence of other intestinal diseases, which seemed to show that the improvement in the enteric figures could not be solely attributed to an improvement in general sanitation.

Abnormalities in the Blood of Cancer Patients

In the *Spisy Lékarské Fakulty Masarykovy University* (Publications of the Medical Faculty of the Masaryk University of Brno (**16**, 97–306; 1937), Dr. L. Havlásek gives an important and lengthy account (with many tables, graphs and 318 bibliographical references) of blood changes in cancerous women. His conclusions are based upon prolonged observations and series of tests made with 57 patients in varying stages of uterine cancer and who were undergoing treatment with radium, X-rays or by administration of certain salts (thiosulphates). The investigation included the determination of the hydrogen ion concentration of blood and urine using the quinhydrone electrode, carbon dioxide determinations and estimations of bicarbonate and hæmoglobin. In addition, the red and the white blood corpuscles were counted and the arterial blood pressure calculated. From these determinations made over a long period before, during and after treatment it was observed that though the results were not uniform there is a definite trend towards the normal figures as the patient approaches recovery.

Flora of Certain Moravian Lakes

The ecology of certain lakes and ponds near Třebíč and Studenec, in south Moravia, is the subject of a recent paper by Dr. F. Nováček (*Proc. Moravian Sci. Soc.*, **10**, 1–70). The lakes which have existed for centuries, lie in the valleys of the Rivers Jihlavka and Oslava, which flow into the Morava and thence into the Danube. The district is studded with pine forests, but with very large clearings. The waters have a sandy bottom, more or less covered with mud and sometimes with humus. More than a hundred species of higher aquatic plants are described and the flora shows a marked zonation with littoral, sedge, rush, loosely attached and floating associations. The condition, composition and extent of the zones is influenced by weather conditions, being markedly different in wet or dry summers. Among the plants in the floating associations, the Lemnaceæ predominate, with *Ricciocarpus* near the banks. *Zygnema* and *Mougeotia* types flourish in June and July whilst *Spirogyra* and often *Cladophora* are abundant in spring and autumn. The plants of the other zones are those usually present in stagnant fresh water, for example, species of *Phragmites*, *Typha*, *Glyceria*, *Alisma*, etc., near the water's edge and *Sagittaria*, *Potamogeton* and *Elodea* towards the deeper parts of the lakes.

Crossing-Over in Chromosomes

Important ramifications of crossing over have recently been reviewed by K. Mather (*Biol. Rev.*, 13, 182–293, 1938). The genetical evidence from euploids and aneuploids, structural hybrids and diploids, together with the cytological work of recent years, establishes the conditions of chiasma formation on a firm basis. The inter-relationships of chromosome pairing, chiasma formation, disjunction and segregation and crossing over are discussed, and it is shown that precise estimation can be made of segregation, linkage and the gametic output of structural hybrids and polyploids. The author also explains his previously published theories, in which he claims that the first chiasma formed is proximal to the centromere, and that there is a localization of the position of the proximal chiasma on the chromosome.

Mycology of the Philippines

THE first two numbers of vol. 65 of the *Philippine Journal of Science* are devoted to a compendious paper on 'Philippine Mushrooms' by José Miguel Mendoza (128 pp. + 79 plates, January–February 1938). The account is written upon a scientific basis, but is designed to instruct the Philippine population in edible and poisonous species. This it does to the extent of outlining culinary uses of various kinds, describing methods for cultivating *Volvaria esculenta*, and indicating the antidotes to fungal poisons. Mycological descriptions are given with sufficient macroscopic detail to allow comparison with other regions, while the plates provide further artistic delineation of many species. A strong European element is noticeable in the flora as here portrayed, but as the text is not critical, any purely Philippine element may not as yet be sufficiently evident.

Seismological Research in Japan

USING Miss F. F. Bellamy's Index Catalogue of Epicentres for 1913 to 1930 as data, Seiti Yamaguti has discussed anew the Seasonal Distributions of Earthquakes in the World (*Bull. Earthquake Res. Inst.*, Tokyo Imperial University, 16, Part 2, June, 1938). It is found that, on the average, the season number with maximum frequency seems to increase from western to eastern longitudes and from northern to southern latitudes, with the second season (June–August) as the mean. When the earthquake frequencies are plotted against the months, it is notable that the curves for Japan and the Mediterranean coast are opposite in phase. The Fourier coefficients for the annual distribution, the relative amplitude of the annual term, and the phase of maximum have all been evaluated and compared with what may be expected as the result of fortuitous happenings. It is found that the times of maximum frequency change in the northern hemisphere from June to November successively, according to latitudes, a succession that is too regular to be attributed to chance. In the same bulletin, Prof. K. Sezawa discusses the "Anomalous Dispersion of Elastic Waves", notably Love waves and Rayleigh waves in certain defined conditions. Altogether there are eighteen papers ranging from pure geology to mathematical seismology; thirteen of the papers are in English and the remainder in Japanese with summaries in English. Accompanying the *Bulletin* is the "Seismometrical Report of the Earthquake Research Institute, Tokyo Imperial University, 1937, Part 3–4 (July 1–December 31, 1937) which gives a list (in Japanese) of earthquakes sensible in Tokyo for the period stated, and which is adjoined to a map indicating the epicentres of these earthquakes.

Atomic Weights and Isotopes

THE reports of the committees on atomic weights and atoms of the International Union of Chemistry (*J. Chem. Soc.*, 1101, 1110; 1938) propose some changes of atomic weights and report some new isotopes. Among the former the most interesting are (older values in brackets): hydrogen 1·0081 (1·0078), helium 4·003 (4·002), and carbon 12·010 (12·01). Attention is also directed to the atomic weight 207·205 found for lead from a specimen of galena occurring in a vein which cuts one of the pitchblende veins of the Great Bear Lake deposit; this appears to be common lead, and if so it is one of the oldest to be examined. A new rare isotope of tungsten (180) and a very rare isotope of osmium (184) have been discovered. It has proved impossible to detect the isotopes 197 and 203 of mercury.

Research at the Cape Observatory in 1937

H.M. ASTRONOMER at the Cape, Dr. J. Jackson, reports that during the year 1937 the large number of 15,490 transits of stars were obtained with the reversible transit circle. During the daytime, 883 observations were made including transits of bright stars in the equatorial belt generally between 9 a.m. and 11 a.m. South African Standard Time. With the 8-inch transit circle, the observation of reference stars for the Cape Astrographic Zone, − 35° to − 40°, was completed; the observation of similar stars for the Zone − 52° to − 56° was commenced. The Victoria telescope—a Grubb photographic refractor of 24 inches aperture—continues to be used for the determination of stellar parallax; 3,476 plates were obtained. Since this programme was started in 1926 at the Cape, the parallaxes of 836 stars have been published. Another 18 parallaxes await publication, including the parallax determinations of the very bright stars, Sirius, Canopus and Antares. The result for Canopus, a super-giant star, indicates a considerably larger parallax than that generally adopted. The Victoria telescope has also been used for photographing galactic clusters south of − 30°, the exposures ranging from 5 minutes to 2 hours. In pursuance of a programme of photographic zone observations, according to methods developed by Prof. Schlesinger, the triplet lens of 6 inches aperture is now being employed on Zone − 52° to − 56°. All plates for the Zone − 30° to − 35° have been measured and reduced, 12,500 stars having been measured in both direct and reversed positions on each of two overlapping plates. The time service and wireless time signals have been maintained. Photographs of the sun were taken on 343 days; these negatives are sent to Greenwich for inclusion in the series to be measured for sunspot positions and areas. The mean temperature for the year was 63·4° F. (mean of maxima and minima), the absolute maximum was 98·0° F. on February 17 and the minimum 38·1° F. on May 16. The total rainfall—the highest since 1905—was 28·12 inches, or 4·69 inches above the adopted normal. In concluding his report to the Secretary of the Admiralty, H.M. Astronomer refers to the valuable services of two members of the staff who have retired on pension, Mr. A. Pilling and Mr. T. R. Miller.

The International Congress of Anthropological and Ethnological Sciences

A SESSION of the International Congress of Anthropological and Ethnological Sciences took place in Copenhagen on July 31–August 6, and was followed by a two-day tour through parts of Denmark for members of the Congress who could spare the extra time required. Actually it was only the second time that this most newly fledged of congresses had met, and its great success testifies to the ever-growing interest throughout the world in the study of man, as well as to the immense trouble taken by the Danish organizers to see that everything should proceed smoothly and without any hitch. More than seven hundred members and associates were present, some 29 countries and 177 learned societies and institutions being represented.

The official opening meeting of the Congress did not take place until the afternoon of August 1, but already there had been a reception on the previous evening to enable members to meet one another. This was an excellent arrangement. After all, the main function of these international gatherings is not so much to facilitate the announcement of startling discoveries as to permit specialists from various countries to meet each other and discuss together their ideas and problems, the papers in general being little more than pegs upon which friendly, often almost informal, discussions can be hung. In this respect, the organization at Copenhagen was perfect. On several evenings there were after-dinner receptions in museums, etc., where innumerable discussions took place, helped by a liberal supply of Carlsberg beer and light refreshments!

The official opening ceremony was dignified by the presence of H.M. the King of Denmark, to whom delegates from several countries were presented. Inaugural ceremonies can easily become somewhat tedious functions: not so this one. His Majesty's presence testified to the importance of the occasion and, further, the proceedings were kept commendably short. Besides the necessary speeches of greeting from some of the national delegates and an oration from Dr. Thomas Thomsen, head of the Department of Ethnography in the National Museum and president of the Congress, there was a short orchestral symphony by Kunzen (1761–1817) which helped to lighten the proceedings. Later in the afternoon there was a motor-bus tour of the city.

On Tuesday morning, the work of the sections began and continued daily until the final closure on the Saturday afternoon, with the exception of Thursday, which was devoted to an all-day excursion. There were seven sections, a number of which were subdivided. From A to G they were severally concerned with physical anthropology and allied matters; psychology; demography; ethnology; ethnography, there being sub-sections dealing with Asia, Africa, America, Oceania, the Arctic and Europe; sociology and religion; linguistics and writing. Obviously it is not possible to discuss all the papers here, for that one must await the publication which will appear in due course. But mention can be made of one or two.

"What is a Human Race?" was discussed in Section A by Dr. Nordenstreng of Uppsala, where, too, Dr. F. Weidenreich tabulated a "Classification of Fossil Hominids" definitely placing the existence of *Homo sapiens* in a period anterior to that of our well-known fossil remains of *Homo primigenius*. Questions of blood groups also came up for discussion in this section. In Section D (Ethnology) a paper by Prof. Hatt on the ownership of cultivated land in early times produced an interesting discussion, as also did those by Prof. Herskovitz on the economic surplus and its disposal and by Prof. Firth on the characteristics of a primitive economy. In this section, too, the problems of the development of primitive agriculture and of the horse in Neolithic times were dealt with by Dr. Miles and Dr. Gandert respectively, as well as the first cultivation of wheat and the spread of agriculture, by Mr. Harold Peake.

The sub-sections of Section E provided a wealth of papers. Perhaps one may mention especially those by Profs. Arik and Kansu on recent excavations and palæolithic discoveries in Turkey and by Sir Theodore Tasker on the archæological wealth of the State of Hyderabad, not that there were not many other papers of importance but because these three bore witness to the anthropological work that has recently been so successfully started in those distant regions. Among other British anthropologists present who read papers were Profs. Hutton and Daryll Forde and Dr. Lindgren. Any account of these sectional papers is, however, bound to be invidious at this stage, since the writer was only able to listen to a limited number and to gain information from his friends who had been to others.

A few joint meetings of various sections took place where slides and films were shown. Thus Dr. Morley demonstrated the results of twenty-five years of research in the Maya area of Middle America, while at another time ethnographical films were projected. A general meeting to see films of Greenland, Old and New, was arranged for one evening, and this was preceded by a talk from Mr. Daugaard-Jensen, the chief administrator in the country, who gave us an impressive account of what Denmark has done and is doing for the Greenlanders.

Throughout the period of the Congress, the National and other museums were open free of charge to members. The National Museum has been recently reconstructed and enormously enlarged. Not only are the prehistoric collections from Denmark and the immense series of Eskimo objects unique in the world, but also the arrangement of the Museum is most carefully thought out. It is not a mere storehouse of specimens: to follow the sequence of galleries is an educational experience. If only the British Museum could be rearranged in a like manner! One evening, a reception was held at the Museum and the closing scene was really emotionally memorable. At 10.30 p.m. everyone assembled in the great courtyard, where there are model megalithic monuments in the open air. Then a museum showcase was opened and two great Bronze Age *Lurer* were taken out and handed to two trumpeters who, standing on some steps above the assembled members, proceeded to play stirring duets upon them. The effect was electric—were we not listening to instruments which had first been played more than 3000 years ago?—and it was enhanced by the knowledge that the performance can seldom be repeated, the authorities being justly fearful lest the vibration might shatter these ancient and beautiful trumpets.

The excursion on Thursday was to Elsinore and the Castle of Frederiksborg. At the former place, in the great hall of Hamlet's Castle, a lecture on "Natural Philosophy and Human Culture" was delivered by the distinguished physicist Prof. Niels Bohr. The municipality of Marienlyst, a seaside resort close to Elsinore, most kindly provided a lunch which was preceded by a display of water acrobatics by Greenlanders in their kyaks—and an astonishing display it was. On the last evening members dropped their science and became ordinary human beings. After a really sumptuous dinner *chez Nimb* they either danced or passed into the Tivoli (Copenhagen's White City), where the learned were seen happily smashing plates at 5 shies for *6d.* or careering madly down the scenic railway—of such is a true League of Nations!

In conclusion, unstinted praise must once again be given to the organizing committee, and in this connexion the name of Dr. Birket Smith must especially be mentioned. He was always helpful and always at hand. Everything worked splendidly, and anyone who has ever had to organize more than 700 people on excursions, at lectures, for entertainments and meals will realize what this means. Nor did the consideration of our Danish hosts confine itself to the full members alone. As always, a number of associates, wives of members and others, were present who might perhaps be expected to be less interested in attending religiously the meetings of the sections, and for these people special activities, including a ladies' lunch at the Yacht Club, were arranged by a ladies' committee. Parties, for example, visited the porcelain works and the not less famous Georg Jensen silver works. There is no doubt that everyone worked very hard to make the Congress the success it was, and certainly their labours were much appreciated. Fortunately, the opportunity occurred to tender the thanks of the guests both formally at the closing meeting and, more informally, a little earlier during an afternoon reception in the Town Hall given by the Municipality of Copenhagen. The Portuguese delegate, when replying to a speech of welcome from the Burgomaster, took full advantage of this opportunity. Finally, in this connexion the name of Prof. J. L. Myers cannot be forgotten. As one of the general secretaries he has had to work hard behind the scenes for many months past to ensure that the gathering should be the very great success it assuredly was. Members and associates will long remember the second meeting of this Congress held in Copenhagen.

M. C. BURKITT

The International Astronomical Union

THE sixth triennial meeting of the General Assembly of the International Astronomical Union was held at Stockholm on August 3–10 under the presidency of Prof. F. Esclangon. The meeting was the largest and most representative held so far, with more than four hundred people present, including nearly a hundred from the United States. Germany has so far not seen its way to join the Union, but there were more German astronomers present than on any previous occasion. The local organization under Prof. H. von Zeipel, Prof. B. Lindblad and an indefatigable secretary, Dr. Y. Öhman, was extremely good, and combined with perfect weather to contribute to the complete success of the meeting.

After the opening meeting, when the Union was welcomed by the Minister of Justice, the president of the Royal Swedish Academy of Sciences and the chairman of the Swedish National Academy of Sciences, the Union settled down to the task of discussing the reports of the thirty-one committees through which its work is carried out between meetings.

In addition to the specialist discussions carried on in these separate small bodies, there were arranged this time two symposia with a wider range of interest —one on the formation of bright lines in celestial spectra and one on the problem of galactic structure.

Sir Arthur Eddington presided over the first meeting and the speakers were Prof. H. N. Russell, Dr. H. Zanstra, Prof. D. H. Menzel and Dr. P. W. Merrill. At this meeting, M. B. Lyot showed slides of his direct photographs of the corona and the coronal spectrum secured at the Pic du Midi and also a striking cinema film of movements in prominences taken by direct photography. This aroused such enthusiasm that it had to be shown on a second occasion during the meeting. It included one remarkable instance of an existing prominence being blown up by an uprush of fresh matter from below, numerous instances of matter flowing upwards and still more frequently of matter streaming horizontally or downwards in striking arch formations. The second symposium was presided over by Prof. Lindblad, and the speakers were Dr. B. J. Bok, Prof. Lindblad, Prof. H. Shapley and Dr. Becker. Dr. Baade's photographs showed what striking advances in photographic sensitivity had been achieved recently in the red.

Both discussions led to useful contributions from other speakers and they formed a valuable innovation. It was felt in certain quarters that the symposia and the lavish Swedish hospitality had encroached to some extent on the time usually allotted to the work of the committees, but the excursions, especially that on a steamer in the archipelago of Stockholm, gave ample opportunity for another and very valuable side of the activities of the conference—the discussions between small groups of colleagues gathered together from all over the world.

Among the resolutions adopted by the Committees and later by the General Assembly, a few may be mentioned as having a field of interest outside too specialist a range. A list of standard notations was agreed to; arrangements were confirmed for studies on early Egyptian and Russian astronomy and a recommendation adopted that the scientific letters of Sir Isaac Newton should be edited and published. Owing to the failure of the world schemes of longitude determination by radio signals carried out in 1926 and 1933, to show any evidence of longitude variation, it was decided to carry out no further scheme of a similar nature for another ten or twelve years at least. Steps were agreed to for hastening the completion of the catalogue of the *Carte du Ciel*, the co ordinates of stars in the *FK3* catalogue were adopted for time determination from January 1 1940 The Union adopted the specification of the primary standard of wave lengths formulated in 1935 by the International Committee of Weights and Measures, and adopted fresh secondary iron standards in the ultra violet and solar standards in the infra red, it also agreed to a standard notation for describing lines A special grant was made towards the expense of reproduction of the Utrecht photometric solar atlas giving the profiles of all Fraunhofer lines from Mount Wilson plates between 3300 and 8900 A

It was agreed to give presidents of commissions wider powers to form sub commissions with the view especially of developing work in subjects bordering on the special work of two or more commissions and an additional commission on inter stellar matters was created

An invitation to hold the next meeting in 1941 in Switzerland was accepted very cordially and the executive committee for the next three years was elected as follows *President* Sir Arthur Eddington (Great Britain) *Vice Presidents* Prof G Abetti (Italy) Dr W S Adams (U S A) Prof O Bergstrand (Sweden) Prof W Brunner (Switzerland) and Prof Ch Fabry (France) *Secretary* Prof J H Oort (Holland)

Humidity in the British Isles

THE importance of humidity as a climatological element has been increasingly realized in recent years Until quite recently however, comparatively few summarized data were available for the use of industrial technologists bioclimatologists and others to whom the humidity of the air in the British Isles is a matter of concern There were in fact only two published collections of average values W F Stacey s averages with charts for 91 stations in England and Wales[1] and Section 6 of The Book of Normals[2] containing hourly averages for five observatories with isopleth diagrams of hourly averages for seven additional stations

In both these publications relative humidity was the only element treated Stacey s averages were based on readings at 9 h during the ten years 1901 10 and his stations were sufficiently numerous to give a fair representation of the average distribution of relative humidity over England and Wales at 9 h It is difficult however to draw any useful conclusions from charts and averages based on observations at 9 h, an epoch at which relative humidity is normally in process of descending from the early morning maximum to the afternoon minimum This limitation will be realized if one imagines how incomplete our information about air temperature would be if we had nothing beyond the readings of an ordinary thermometer at 9 h

Apart from relative humidity, there are at least two other hygrometric elements for which scarcely any summarized data have hitherto been available namely vapour pressure and moisture content Averages for the principal observatories are given in Bilham s Climate of the British Isles[3] but it is clearly desirable that values of these two important elements should be available for a large number of stations

These needs have now been met by an official publication* recently issued In view of the fact that the book contains an explanatory introduction 21 pages of tabular matter and 26 charts it may be described as extraordinarily good value for money The main table contains monthly and annual averages for 44 synoptic stations, six columns of data being given for each station The first four columns refer to 13 h and contain 15 year averages of air temperature, relative humidity, vapour pressure in millibars, and moisture content in grams per cubic metre The remaining two columns contain averages of relative humidity at 7 h and 18 h In Table II we have hourly averages of relative humidity at nine stations These have in the main been reprinted from previously published averages for first order observatories, but data from two new stations Sealand and Cranwell have been added to improve the geographical distribution Table III contains hourly averages of vapour pressure at Kew and Eskdalemuir This is followed by an appendix containing the standard values of the vapour pressure and moisture content in saturated air at all temperatures from 0° F to 120° F These are based on the determinations of Scheel and Heuse and are given to two places of decimals[4] In combination with the data contained in Table I they afford the means of calculating average values of such quantities as saturation deficit and dew point the methods of doing so being explained in the introduction

The charts show the distribution of relative humidity and vapour pressure at 13 h over the British Isles in each month and the whole year The scale though small is sufficient to display the general features of the geographical distribution and to permit of the possibility of interpolating values for particular places with fair accuracy The charts show that the distribution of mean relative humidity at midday is as might be expected complementary to that of mean maximum temperature the lowest values being found in the inland areas where the afternoon temperature is high In addition there are clear indications of Föhn effects in winter months, patches of relatively dry air being located along the Great Glen on the east coast of Scotland and along the Welsh border The dry air during the night hours in the Great Glen results in Fort William having the lowest daily mean humidity of the nine stations for which hourly averages are given Another interesting fact revealed by the new data is that at Eskdalemuir in the southern uplands of Scotland, the diurnal range of vapour pressure is substantially greater than at Kew in summer months It is impossible in this article to enter upon any general discussion of the data but it is clear that this publication contains sufficient information to meet the needs of most inquirers

Reclamation of Tidal Lands

IN the *Journal of the Royal Society of Arts* of July 15, 1938, there is published the paper read before a meeting of the Society on February 23 by Mr. Oscar Borer, chief engineer of the River Ouse Catchment Board, in which he gave a survey of the reclamation of tidal lands which has been proceeding on both sides of the North Sea. In a brief note on the geological history of this sea, the author shows that, whether it be accounted for by one theory or another, its water holds in suspension a fine sand or silt which was ground to its present state during the glacial period. This silt only settles in quiet protective bays where the flood water can come to rest; the aim of the work of reclamation is therefore to create those favourable conditions requisite for the extension of the land from the enormous stock of silt provided by Nature. Nature not only provides the material but also constitutes the agency by which the main operations are carried out. Here the engineer exercises his highest function in studying the methods of Nature and in directing them so that they benefit mankind

'If the natural process of accretion be not assisted by artificial means it becomes stationary after reaching a certain distance from the shore, because beyond that distance the movement of the flow and ebb of the tide does not admit of the quiet conditions favourable for deposit. When a sea marsh is enclosed by a bank, the movement of the water is restricted, and, outside the bank, accretion takes place rapidly, so that in a few months the sand becomes covered with warp This is followed by a growth of samphire, which is, in turn, succeeded by grass, so that eventually the surface consists of a fine mass of warp mixed with roots of grass and decaying vegetable matter. In the course of a few years this process results in the production of a highly fertile soil which, however, must not be enclosed until a sufficient number of years have elapsed and the land thus reclaimed has become 'ripe'—a process taking about twenty years Meantime, of course, no accretion beyond this is taking place, so that it will be realized that the work is such as to demand patience, foresight and continuity in its direction.

In the course of the lecture, many details were given of the work carried out since Roman times and of the different methods adopted in the operations at the Wash, in the Netherlands and on the German North Sea coast, at each of which the necessary favourable conditions exist. Mr. Borer also mentioned the various plants and grasses which assist the work and the order in which they appear.

Science News a Century Ago

British Association at Newcastle-upon-Tyne

ON taking the chair of Section A (Mathematical and Physical Science) of the British Association, on Monday, August 20, 1838, Sir John Herschel said that the Committee had decided on the order of proceedings for the Section, but it had been found difficult to arrange matters, as although notices of abundance of communications had been received, few papers had come to hand and it was almost impossible to get in touch with contributors owing to a lack of knowledge of their addresses. The part of the proceedings he considered most valuable and important was the opportunity to ask questions. In exercising this privilege members, however, would do well to condense their remarks.

Importance of Meteorological Data

AMONG the contributions to Section A of the B.A. at Newcastle-upon-Tyne was "A Report explaining the Progress towards developing the Laws of Storms" by Lieut.-Colonel W. Reid, R.E. His attention, he said, had been first directed to the subject in 1831 when he was on military service in Barbadoes. A hurricane had occurred just before he arrived in the colony and for two years and a half he had been employed among the buildings which had been ruined In the course of his paper he referred to the observations of Benjamin Franklin and of Col. Capper of the East India Company, the writings of W. C. Redfield of New York, the anemometers of Whewell and Osler, and he pointed out the desirability of preserving the logs of ships, and of inducing the several maritime nations to establish registers at their lighthouses, and mutually to communicate their observations

Waves and Water Resistance

To Section A and also to Section G (Mechanical Science), John Scott Russell contributed papers on waves and the resistance of water He and Sir John Robison, he said, had been constituted a committee to prosecute the investigation of the motion of waves and other problems in hydrodynamics. As to the general problem of the resistance of a fluid to a floating solid, this was a department of science of which we were avowedly ignorant; so much so that some of our best vessels were acknowledged to be constructed by rule of thumb The question of resistance resolved itself into that of the motion of waves. Waves were of various kinds The laws of the great primary wave had been laid down in previous communications. Its velocity depended simply on the depth of the fluid The old law of resistance, as the square of the velocity, was too small so long as the velocity of the solid was less than that of the wave, but too great so soon as the velocity of the solid becomes greater than that of the wave.

Structure of Teeth

THE most important paper before Section E (Medical Science) was that on the structure of teeth and the resemblance of ivory to bone, as illustrated by microscopical examination of the teeth of man, and of various existing and extinct animals, read by Richard Owen, then Hunterian professor and joint conservator of the Hunterian Museum. Until recently, Owen said, the analogy of tooth to bone was supposed to extend no farther than related to the chemical composition of the hardening material, while the arrangement of this earthy constituent, as well as its mode of deposition during the growth of the entire tooth, were considered to be wholly different from those of bone, and to agree with the mode of growth of hair and other so-called extra-vascular parts, with which the teeth undoubtedly closely correspond in the genera vital properties. Owen referred at length to the work of Prof. Retzius of Sweden, and explained the views he himself held on the analogy subsisting between tooth and bone, illustrating his observations by description of teeth of both living and extinct species. Through the endless diversity which the teeth of different animals present, he said, the general law of the tubular structure could be unequivocably traced.

The Progress of Science in India

IT is one hundred and three years since Macaulay wrote his famous minute on education in India, in which he stated that it was impossible, with the limited means available, to attempt to educate the body of the people This century has seen an amazing development in all directions Politically, self-government has been largely achieved and this has been rendered possible by the adoption, as advocated by Macaulay, of English as the medium of education English has become the *lingua franca* of the Peninsula, and the mass of the discussions in the legislative councils is conducted in that language. But there has occurred another, if less dramatic, change. An educational ladder has been provided which has opened a clear road from the village primary school to the university In the space of a century, India has passed from a social state with an aristocracy as strongly marked as in the Norman period, with a priestly hierarchy as dominant as in the palmy days of the monasteries and with the mass of the people in a state of serfdom equally reminiscent of those early English days, to a state with all the democratic institutions of modern England and with an industrial development of no mean proportion if, as yet, small when judged by the percentage of population so engaged.

In this movement science, both pure and in its application, has received its full share of attention Science, in its modern sense, found its first footing in India in 1784 with the foundation by Sir William Jones of the Asiatick Society; now known as the Royal Asiatic Society of Bengal, and that footing was extended and fortified by other societies of which the best known is the Bombay Natural History Society founded in 1883. These were unofficial ventures. Officialdom took longer to recognize the status of science. In those early days, certain services clearly lay beyond the capacity of the civil administration as established by the East India Company For these, special services had to be instituted, a medical service, first established as distinct from the Army medical service in 1763, and a trigonometrical survey in 1800, which were staffed from the only technical source available, namely, the Army.

With a growing recognition of the need for specialized knowledge in other fields, it was only natural that the civil authorities should turn to the same source to find the cadre Thus, to mention one sphere only, botanical work was entrusted to men of the medical services who, as such names as Roxburgh, Royle, Wallich, Prain and Watt testify, laid a solid foundation for later building, while, to mention the other service as well as to sound a personal note, an Army engineer, an uncle of the present writer, became controller of the mint

But science was moving fast, particularly in its application to the everyday facts of life It was also becoming more specialized, and something more than diversion of the talent existing in these established services was required India is an agricultural country still, and was even more so at the end of the last century, when great strides were being made in the application of science to agriculture in temperate countries. To Sir Edward Buck falls the credit of realizing the need for investigating the fundamental problems of Indian agriculture and the special nature of these problems Thus came to be employed a group of specialists—Leather, Barber, Butler and Maxwell Lefroy are names that will be recalled—later, in 1903, to be incorporated into one service, the Indian Agricultural Service, with its imperial branch at Pusa and a provincial branch in each province.

Two motives can be traced in the above noted developments The first of these is that general thirst for knowledge which at first finding outlet in private directions afterwards became translated into official action Thus the Botanic Gardens of Calcutta founded in 1788 became the centre of the Botanical Survey of India in 1889 an Archæological Department was established in 1862 while the foundation of the Indian Museum in 1866 provided a centre for this and for the study of natural history The second was the growing economic importance of many sciences The Geological Survey was established in 1851 the Indian Marine Survey Department in 1871 a Fisheries Department in 1870 and a centralized Meteorological Department in 1872

In all these movements it was the British who provided the impetus Here and there Indians played their part Ram Mohan Roy who so early as 1816 took a prominent part in founding a Vidyalaya afterwards to become the Hindu College and later the Presidency College Calcutta Sir Ashutosh Mookerjee Sir Jagadis Bose and P N Bose The reason for this is to be traced to the lack of facilities for and the inadequate organization of higher education the potentialities of the Indian for advanced studies had not yet been appreciated Though universities had been established at Calcutta Bombay and Madras in 1857 at Lahore in 1882 and at Allahabad in 1887 these remained examining bodies and teaching was relegated to the affiliated colleges where facilities were inadequate for original work even by the staff whose time was absorbed in teaching and still less for postgraduate work It remained for the Universities Commission of 1902 to transform the universities into teaching bodies with the allocation of large grants for higher education a policy further implemented by the establishment of a separate Department of Education in 1913

Thus the beginning of the century marks an epoch and the progress made since then has been remarkable No adequate presentation could be given in a brief article such a presentation is contained in the volume of nearly eight hundred pages* recently published It requires no detailed turning of these pages to realize from the names of those whose work is quoted how quick the Indian has been to take advantage of the facilities thus newly thrown open to him The volume has been produced to celebrate the silver jubilee of the Indian Science Congress Association which held its first meeting under the presidency of Sir Ashutosh Mukhopadhyaya (Mookerjee) in the spring of 1914 This Association owes its origin to a realization of the growing need for some means of bringing together the increasing number of workers in the various scientific fields and it adopted as its fundamental plan and conception the principles of the British Association

India is a large country and the danger of isolation is greater there than in relatively small England The need for some means of co ordination early became apparent The Board of Agriculture with its annual and later biennial meetings served that function for the newly instituted agricultural services though owing to its official status and its reviews of programmes of work it ran grave risk of adopting a dictorial attitude Since 1929 its functions have largely devolved on the Imperial Council of Agricultural Research In 1902 a Board of Scientific Advice was established but suspended in 1924 and in 1911 the Indian Research Fund Association was founded mainly to co ordinate research on the causation mode of spread and prevention of disease

It was to provide a field in which a co operative spirit rooted in personal contacts rather than in co ordination a word which savours of officialdom and dictation that constituted the primary objective of the Association—a field free from official dictation but having the official blessing That it has gone a long way to achieve its purpose is undoubted but that it has not entirely succeeded —is any human institution an unqualified success ? —its foremost advocates would be the first to admit The concept of the British Association has perhaps been too closely followed This Association serves two functions it forms a common ground on which scientific men may meet and so counteract the dangers of specialization and it has the further objective of the dissemination of scientific thought among a wider public That latter objective is perhaps the dominant one but, in India the public which can be so influenced is small The feeling of incompleteness whatever its cause is there and has found expression in the institution of supplementary societies the Academy of Sciences United Provinces founded at Allahabad in 1930 the Indian Academy of Sciences founded at Bangalore in 1934 and the National Institute of Sciences of India founded at Calcutta in 1935 Scientific organization thus is proceeding in India centrifugally Instead of a central body arising as a coping stone, around this earlier central body are coming into existence a number of loosely linked associations each with its local sphere This difference has significance.

* Indian Science Congress Association Silver Jubilee 1938 The Progress of Science in India during the past Twenty five Years Edited by Dr B Prashad Pp lvi+767 (Calcutta Indian Science Congress Association 1938) 5 rupees

India has demonstrated that it is capable of producing men with a scientific ability which would do credit to any country, but the very speed with which it has attained this position has its dangers. If, in conclusion, these are briefly indicated, it is in the spirit of the friendly criticism of one who remembers many happy years spent among its peoples It appears to such a writer that the major danger arises from the entry of India into the scientific field at a time when the application of science to economic problems had proceeded far It was this pressure that provided openings for a livelihood in scientific work and it was the Government that mainly created those openings. Science may easily, in these circumstances, lack the stabilizing effect of a nucleus of disinterested men studying for studies' sake, and tend to become merely a means of earning a living; and it is difficult to regard a potential competitor for a post with true scientific detachment It is a danger from which Great Britain is not free but one which is emphasized in a country where university education is primarily sought as a qualification for employment and where pre-university education remains in many respects defective These are, however, growing pains; with ability undoubtedly present, with the will to develop the true scientific spirit which clearly exists, who can doubt the future of science in India?

H. M. L.

The Credo of an Anthropologist

Apes, Men and Morons

By Prof. Earnest Albert Hooton Pp. ix + 307 (London: George Allen and Unwin, Ltd, 1938) 10*s*. 6*d* net

IF a credo is to have value, it must be enunciated by one who has several outstanding qualifications. In the first place, it must be based on a prolonged personal experience of a particular branch of knowledge. Prof Hooton has this qualification; he has been teaching physical anthropology to the students of Harvard University for more than a quarter of a century In his earlier years he made a detailed report on the bones and culture of the peoples who had inhabited the Canary Islands; later he did the same for Pueblo Indians. In more recent years he has devoted himself to a physical and social study of his fellow countrymen. Of these about 6,000 had been isolated in penal institutions; his "controls" were taken from those "not yet apprehended" The full results of ten years spent in a "statistical purgatory" have not yet been published but in this book he gives in the midst of his general discourse a summary of his chief conclusions. He has found that those within the walls of penal institutions are inferior in body and in mind to those who live outside, and that already in the United States of America the population is becoming differentiated into local types.

Prof. Hooton has the knowledge, but knowledge alone is not sufficient to make a credo worth listening to. Knowledge must be linked to a sound judgment, and ultimate beliefs must be uttered with a resolution which is fearless of popular opinion It needs as much courage to run counter to the prejudices of a democracy as to face the wrath of an autocracy "For myself," Prof. Hooton has written, "I prefer to be the target of rotten eggs rather than to be suspected as a purveyor of that odoriferous commodity" He refuses to "side-step the issues which are vital and dangerous" and seeing that he discusses the problems of 'race', religion and sex, a less courageous man would have been tempted to "side-step" at every turn. Prof Hooton, too, has the saving grace of humour; his pages scintillate

A book which is made up, like the present one, of lectures and articles, is apt to be disjointed and over-lapping. There is no trace of these faults in the present work Its pages discuss in sequence the various phases in man's ascent from the jungle. Especially is its author concerned with the impact of his science on the community His attitude will be conveyed by an extract from his final chapter entitled: "What must we do to be Saved"?

> "We must either do some biological house-cleaning or delude ourselves with the futile hope that a government of the unfit, for the unfit, and by the unfit will not perish from the earth.
>
> "We must, in some way or other, encourage a sit-down reproductive strike of the busy breeders among the morons, criminals and social ineffectuals of our population. . . We must inculcate into the rising generation a code of biological ethics . . . The emergency demands a surgical operation."

I, for one, refuse to take Prof. Hooton's "obstinate pessimism" in all its implications; nevertheless, his is a vigorous and timely call to action —on the part of everyone.

A. K.

A Highway Code for Vitamin Workers

The Biological Standardisation of the Vitamins By Dr Katharine H Coward Pp viii + 227 + 7 plates (London Baillière Tindall and Cox 1938) 12*s* 6*d*

INTERNATIONAL standards for certain vitamins have been in existence since 1931 The experience of the last few years has shown that while they have been accepted readily throughout the world a number of workers have either failed to make proper use of them or have not interpreted the results correctly The errors are of commission as well as omission and a rooted dislike and fear of the mathematical unknown lying beyond a simple average—usually drawn from too few animals—seems to be the most common sin

Dr Coward and her colleagues of the Pharmaceutical Society have for some time been leading a courageous missionary campaign among the unbelievers and have published many papers mostly in the *Biochemical Journal* describing how to carry out vitamin assays and how to make proper use of animals and of mathematics These papers form the basis of Dr Coward s book Much new information has been added and the author must be heartily congratulated on this timely collation

The book is in two parts of which the first is self contained and describes the practical aspects of vitamin estimation The reader can make use of this part without first having to master the second which deals with statistical methods of interpretation Nevertheless the second part is extremely simply written and as the author points out in her preface it is to be hoped that workers who have been accustomed to fight shy of statistical methods will be encouraged to take the plunge

Part 1 opens with a very concise account of the general principles of biological assay and of the selection and care of experimental animals The following chapters deal separately with methods for the estimation of vitamins A B_1 C and D that is of all the vitamins for which international standards have been adopted The final chapter of Part 1 describes the way in which certain vitamins affect the estimation of other vitamins

Part 2 outlines the rudiments of the statistical methods which are necessary for biological estimation It then deals with the application of these methods separately to each of the vitamins Copious numerical illustrations are worked out in full in each case The factors governing the standard of accuracy are explained and the way in which an experiment has to be designed and the number of animals chosen to attain a given standard of accuracy is most happily described

Dr Coward writes almost entirely from first hand knowledge and thus imparts to the book a pleasing vitality and directness of style She is a recognized master in the field of vitamin research and few authors have had her opportunities of trying out most methods selecting a few and testing them over a period of years on a large number of animals Her vast experience enables Dr Coward to give the reader invaluable practical hints as to what should be done in the general planning of biological assay Perhaps more important still is what she has to say about things which should not be done

The book does not aim as many compilations do at giving a glossary of all existing methods indeed the author only rarely cites methods not in regular use in her own laboratory and then only on the best authority As she wisely points out a technique of assay found successful in one laboratory often fails in another The principles of interpretation remain however unchanged In working out the technique best suited to his own laboratory and in interpreting his results the reader could not do better than follow the advice contained in Dr Coward s book

Like every piece of pioneering work the book is not faultless but its merits heavily outweigh its few shortcomings In fact it is so good that it will doubtless become a standard book of reference

Owing possibly to the method of presentation the book contains a certain amount of repetition which a specialist might feel inclined to delete but which will be welcomed by the reader approaching the subject for the first time Some pruning should however be possible without loss to the latter for example it is scarcely necessary to give on pages 27 125 and again on page 134 the detailed composition of the same salt mixture

The statistical part of the book is so lucid and is likely to be used as a model by so many readers that it is a pity that the author has not mentioned the refinements introduced by Student since

1908 "Student" showed that the limits of accuracy calculated by the older formulæ (which are those used by Dr. Coward) are always somewhat too optimistic, the more so the smaller the number of animals used. In the case of an estimation of vitamin B_1, with only five or six animals per group, Dr. Coward's formulæ would lead to a considerable over-estimate of the standard of accuracy The correct result can be found by entering the t-table (Fisher, "Statistical Methods for Research Workers", fifth edition, 1934, p 158) in place of the table quoted by Dr. Coward on page 150 of the book under review

Of serious errors there are few, and only two are likely to mislead the reader. on page 156, the three square-root signs should be deleted, and on page 162, σ in the text, the figure and the title to the figure should in each case read ϵ By an obvious slip the word "ingestation" is consistently used for "gestation" on page 9 *et seq* On page 21 in the equation of the straight line the second y should be $\bar{y}$ On page 29, line 20, "uncertain" should read "certain"; page 37, line 14, "cod liver oil" should read "test substance", page 48, line 17, "603" should read "606"; page 148, line 24 would be clearer if the second "of" were replaced by "in"; and on page 157, μ^4 of the fifth equation should be μ_4 and μ^3 of the sixth equation should be μ_3 In a few cases authors' names are given in the text, but not in the bibliography, for example, Peters on page 67, and Phillips (1934) on page 143.

Dr Coward writes so clearly and has succeeded so well in giving a presentation of 'statistics without tears' that the few passages of her book which are less clear may be pointed out in the hope that she will find it possible to revise them for the next edition Thus on page 16 the paragraph on the potency of cod liver oil in different solvents will puzzle the reader who may not yet realize that the differences lie within the limits of biological accuracy The paragraph beginning at the bottom of page 46 may also present difficulties The author has set herself too hard a task in attempting to explain Gaddum's statistical procedure to the non-mathematical reader in the brief compass of pages 177–179 The first part of section E on correlation coefficients (page 202) has also suffered from the need of compression

These few errors of a first edition can easily be corrected They do not affect the fundamentally sound structure of the work

The book is eminently readable and should prove extremely popular One finishes its pages impressed and grateful, and one wishes that it were possible for the centres distributing the international vitamin standards to send to each new recipient a copy of this "Highway Code for Vitamin Workers"

Iraquian Hydrology

The Régime of the Rivers Euphrates and Tigris: a General Hydraulic Survey of their Basins, including the River Karun, having particular reference to their Lower Reaches within Iraq, with Information for the Use of Irrigation Engineers, etc By M. G. Ionides. Pp. vii + 278 + 1 plate (London: E. and F. N. Spon, Ltd, New York. Chemical Publishing Co., 1937) 32*s*.

AMONG the great rivers of the world, the Euphrates and the Tigris stand out with peculiar prominence, not that they are of unrivalled length—there are at least a score of rivers of greater or equal magnitude and mileage—but because they are intimately associated with the infancy of the human race. The earliest written records of humanity are linked with Mesopotamia, now absorbed in the country of Iraq, and from the beginning of history the Euphrates was "the great river" (Genesis xv, 18). The closely adjacent basins of the Euphrates and the Tigris were, in fact, the home of the Sumerians, the race to which is credited the oldest form of connected script, the cuneiform.

There is a special interest, then, attaching to a volume which sets out to put on record, for the first time in systematic form, observations of the hydraulic characteristics of these two rivers, and Mr Ionides is to be complimented on the painstaking care with which he has assembled his material and collated his data He acknowledges in the preface that his readings cover a comparatively short space of time and that a long term of records is very desirable This is undoubtedly true, since the characteristics of most rivers cannot be accurately and fully delineated from short-period observations, but still a beginning has to be made, and though for engineers the present study must be considered as provisional and likely to be outdated, yet the information it contains will always have permanent value as a contribution to the fuller knowledge of the future. Mr Ionides expresses his indebtedness for advice and assistance to Mr W Allard who was director of the Irrigation Department of Iraq from 1928 until 1933 and attributes to him the existence of records in a statistical form amenable to analysis Mr Allard is now serving the Ministry of Health in Great Britain and has been lent to the Inland Water Survey which at the present time seems to be scarcely so far advanced as that of Iraq

The drainage system of the Euphrates and Tigris is bounded on the northern and eastern sides by ranges of mountains which form a consecutive series of catchment areas with outlets facing south to south west The south western side of the basin lies on the edge of the Syrian desert and slopes gently inwards towards the Persian Gulf It is to be noted that there is a pronounced difference in the physical conformation of the courses of the two rivers The catchment area of the Euphrates is fairly compact and below its confluence with the Khabur the river traverses arid and desert country for more than 700 miles without receiving any influents except insignificant storm water drainage The catchment area of the Tigris on the other hand is feather like and the river receives numerous tributaries exclusively however along its eastern bank Although the basin lies within four countries Turkey Syria Iran (Persia) and Iraq it is to the last named which includes the territory formerly known as Mesopotamia that the river discharge is of chief value and indeed of vital importance

The cultivated area of Iraq comprises two zones the rainfall zone and the irrigation zone In the latter there are about 51 000 square kilometres (20 400 square miles) capable of cultivation of which 40 490 square kilometres (16 200 square miles) are actually cultivated while the river supply is probably sufficient to irrigate annually about 30 000 square kilometres (12 000 square miles)

The foregoing facts are of interest but they are merely introductory to the main theme of the volume Chapter ii describes processes of observation and presentation of data by methods more or less generally in vogue The gauges employed are of two types one a post marked with a graduated scale and the other a set of masonry or concrete steps to which scales are affixed The question of the datum is as yet a little indeterminate There is the G T S or Great Trigonometrical Survey datum but in out of the way places where precise levelling has not yet been done an arbitrary datum is adopted Most of the gauges are read once a day a few more frequently and a few once a week Chapter iii deals with the climate which on the whole is sub tropical and arid Nowhere in the basin is the rainfall heavy while on the plain it is very scanty Temperatures on the plains range from a cool winter to a very hot summer Frosts in winter are fairly common July and August are the hottest months with a mean daily temperature of about 95° F (between 111° F and 79° F) Records of rainfall except at Basrah and Bagdad do not cover a period of more than a dozen years and (up to 1934) yield local averages varying from 49 mm to 607 mm (2 in to 24 in)

Four subsequent chapters constitute a series of detail studies dividing each river into two sections the Euphrates from its source to the Hindiyah Barrage and thence to the Shatt El Arab or combined stream and the Tigris from its source to Bagdad and thence to the Persian Gulf Thereafter follows an examination of three features of river hydrology river bed instability and silt forecasting and floods The underlying principles of river bed instability are discussed and figures are given of general and cross sectional instability coefficients the latter of which reach a maximum at Bagdad and Kut of ±1 1 metre (3 5 feet) Forecasting is an uncertain function in the present state of knowledge and the need for trustworthy seasonal predictions of water supplies available for distribution can only be met by more extended observations in the respective catchment areas The two rivers have their source on opposite sides of the same watershed but owing to the longer course of the Euphrates before reaching the plain danger region the Tigris flood peak tends to arrive about a week earlier

In the chapter on floods the author emphasizes the difficult nature of forecasts and affirms that he has not hesitated to give estimates in which imponderable experience (to wit local knowledge and hearsay) plays a large part He follows Hazen s method in computing per cent chances and his nomenclature and tabular statistics are given on these lines Notable occurrences include the 1929 flood on the Euphrates estimated to be the highest for a period of thirty six years when the maximum discharge was 5 300 cubic metres per second (187 000 cusecs) and the 1935 discharge of the Tigris at Mosul estimated at 7 000 cubic metres per second (247 000 cusecs) These may be compared with the Thames record flood of 37 000 cusecs in 1894

There are a useful bibliography a coloured map, and an index The book is well printed and the diagrams seventy nine in number are clear Altogether the volume will be of undoubted service to geographers hydrologists and other geophysicists and pre eminently to river control and irrigation engineers especially naturally to those engaged in the region of Iraq

BRYSSON CUNNINGHAM

An Encyclopædia of the Air

The Air and Its Mysteries
By C. M. Botley. Pp. xv+296+16 plates. (London: G. Bell and Sons, Ltd., 1938.) 8s. 6d. net.

IF Miss Botley had reverted to the old custom of using sub-titles when she christened her substantial volume, recently published, she could have hit on none more appropriate than "Inquire Within upon Everything connected with the Atmosphere". Meteorologists are perhaps somewhat prone to regard the earth's mantle of gases as the joint province of their own and the aviation fraternities: this book comes as a salutary reminder of the important part played by the air in almost every ramification of human activity. Here is matter that concerns physicians, physicists, psychologists, geographers, astronomers, seismologists, archæologists, photographers, botanists, ornithologists, entomologists, chemists of both the organic and the inorganic variety, radio workers, business men, shipmasters, with, of course, meteorologists and airmen, and, last but not least, lovers of the beautiful in Nature. To each and every one of these the author offers food for thought, supplemented in several cases by suggestions for mutual co-operation or original investigation.

In so doing, the author displays a range of knowledge that is rare in these days of specialization. So encyclopædic is the array of information set forth in her 290 pages of text that it may be doubted whether even the most omniscient reader of NATURE could go through Miss Botley's book without adding something to his stock of wisdom. For he who understands the muscular structure of birds and bats, and who knows that the house-fly moves its wings more than 300 times in a second, may well have neglected to inform himself of the maximum possible size of raindrops, and of the fact that the earth's atmosphere is at least 625 miles thick.

The author has the gift of a pleasant, lucid style, coupled with no small literary grace, evidently resulting from wide and well-chosen reading outside, as well as inside, the realms of science. On one point Miss Botley gives a more accurate statement of the truth than Prof. D. Brunt in his book "Weather Science for Everybody". According to the latter authority, there are "zones of silence" around the seat of *any* great explosion: Miss Botley rightly tells us that this does not happen in the case of an extremely violent explosion, such as the eruption of Krakatoa on August 26–28, 1883, when the detonations were heard at all distances up to about 3,000 miles.

It would really need a corps of reviewers to deal adequately with the multitude of aerial subjects discussed in this volume. So far as the meteorological sections are concerned, there is not much to criticize. An understatement appears on p. 111, where it is implied that the annual average of 143 thunderstorms at Leon, Mexico, is not known to be equalled or exceeded elsewhere on earth. We have the good authority of Dr. C. E. P. Brooks ("Climate", Ernest Benn, 1929, p. 126) for pointing out that Buitenzorg, Java, ordinarily suffers such storms on as many as 322 days in the year. To redress the balance, p. 183 of Miss Botley's book contains what must surely be an overstatement: "On the eastern side of Hudson Bay . . . so cold are the conditions that, in an area five times the size of England, there is not a single tree, only creeping willow".

Attention has recently been directed to a strange lack of unanimity in regard to the world's recorded extremes of low temperature. For the absolute surface minimum at Verkhoiansk (Siberia) Miss Botley, following the *Meteorological Glossary* (M.O. 225, ii), gives − 93·6° F., on January 3, 1885. In various authoritative works the figure is cited as − 90° F. Doubt exists also as to the date of the occurrence, February 1892 being adopted by some Soviet writers, who ought to know. The absolute upper-air minimum, over Java, is said by Sir Napier Shaw to be − 135° F. McAdie, however, puts it at − 133° F., the *Meteorological Glossary* at − 131·6° F., and Miss Botley at − 131° F. How, therefore, has all this promiscuity arisen?

The work under review is well worthy of the high company with which it rubs shoulders in Bell's Popular Science Books. Mention should be made of the fine series of photographic illustrations, outstanding among which are Plates II, X, XIII and XIV, representing respectively a sandstorm over the Pyramids, an example of ball-lightning, the 'banner' cloud on the Matterhorn, and a Fulmar petrel in process of 'banking'. Incidentally, the position of Plate V (an infra-red photograph of the coasts of south-east England and northern France taken from the air) is wrongly given in a reference on p. 202.

E. L. HAWKE.

Essai sur les fondements de la géométrie Euclidienne

Par *Julien Malengreau* Pp *311* (*Lausanne et Genève* Payot et Cie 1938) 8 francs

M MALENGREAU conceives the object of a geometrical treatise to be that of investigating the point aggregates of a space which has been generated by the help of appropriate postulates In the present essay, he has set himself the task of generating the most elementary space which can be the object of Euclidean geometry, where Euclidean space is understood as that space which corresponds to the conditions of our environment according to such immediate verifications as we possess The method whereby M Malengreau obtains this elementary Euclidean space is based upon the generation of aggregates containing an indefinite number of points from those containing only a definite number Such a process necessitates the consideration of all those intermediary aggregates which are of use in classifying the new points as they are obtained But M Malengreau is careful to introduce as few new definitions as possible although he invents several new terms to apply to aggregates which are termed differently in classical geometry and in some cases uses the familiar terms in a different sense from that of classical geometry

From the outset, his method differs radically from that of classical geometry the definitions postulates and theorems being introduced in logical order according to the indispensability of the ideas which they define and explain and then only to the extent necessary to enable them to generate a new fundamental aggregate But M Malengreau points out that it is not possible to pass from an aggregate of lower to one of higher order until the extensions of the members of the former in order and magnitude have been determined

M Malengreau maintains that the elementary space generated by his method is equal in experimental value to the general Euclidean space of classical geometry and his treatment is original enough for one to anticipate with interest the general treatise on geometry which he is planning and to which this essay serves as an introduction

Hydrophobic Colloids

Symposium on the Dynamics of Hydrophobic Suspensions and Emulsions held at Utrecht on the 5th and 6th November 1937 under the auspices of the Colloidchemistry Section of the Nederlandsche Chemische Vereeniging Pp 181 (Amsterdam D B Centen s Uitgevers Maatschappij, 1938) 4 florins

THIS book forms a testimonial to the work of the Dutch school on hydrophobic colloidal solutions It contains a number of papers on the electrical double layer, including one of special importance by H C Hamaker, who discusses stability in terms of potential curves Ionic exchange is then discussed and the book ends with two papers on emulsions It should be read by all workers on colloids, but with certain reservations The best comment is provided by Prof Kruyt at the end of his introduction He says To-day colloid chemistry floats in water ! All our results are confined to an ionising intermicellar liquid and I can scarcely think of any satisfactory way of extending these discussions to non aqueous systems But why try ? It must be realized that colloidal solutions fall into two main classes First there are those the stability of which is due to an ionized surface layer, which may be formed by adsorption of ions as in hydrophobic sols or which may be due to the presence in the particles of ionizable groups The particle may be a polymer molecule or a micelle for example, proteins and soaps Secondly there is the rapidly growing class of substances which form stable solutions because they are soluble in the solvent and which are colloidal because of their large molecular weights for example rubber and the polymers generally There is no reason why this dualism should be more disturbing in two dimensional chemistry than in ordinary three dimensional chemistry It is not a bar to progress, but a clear indication of how far a particular line of attack can be followed profitably

Discarnate Influence in Human Life

a Review of the Case for Spirit Intervention By Ernesto Bozzano Translated by Isabel Emerson (Library of the International Institute for Psychical Research, Vol 1) Pp xiv + 274 (London International Institute for Psychical Research , John M Watkins n d) 8*s* 6*d*

IN this volume Signor Bozzano, one of the most prolific of Italian writers on psychical research sums up the conclusions to which he has been led in the course of many years of attention to this subject The book will be of some considerable interest to spiritualists since it attempts to deal in detail with the difficulty of combining in one so called explanation, phenomena where resort to a spiritistic hypothesis is clearly unnecessary, and other manifestations where the influence of the discarnate might to some minds be considered obvious

Signor Bozzano advances the view that it is not a situation where the choice is between what he calls animism and spiritualism but that it is one where the two are combined and interlinked to such an extent that it may be said that animism proves spiritualism The subliminal processes are, to Signor Bozzano the senses of the spirit still incarnate, which are only later to emerge and function in the environment proper to them Thus instead of being an all sufficient explanation of psychic phenomena they can be regarded as pointers to the only true explanation, namely, the activity of spirits still incarnate which, when released from the body at death, fulfil their destiny in spiritual realms

Although the theory will scarcely be considered by those to whom the existence of psychic phenomena is still in doubt, it will certainly be discussed at length by psychical researchers generally, to whom this book, so well translated by Isabel Emerson, can therefore be commended

The Pleistocene Anthropoid Apes of South Africa

By Dr. R. Broom, F.R.S., Transvaal Museum, Pretoria, South Africa

DART'S discovery in 1924 of the fossil ape of Taungs, which he named *Australopithecus africanus*, opened a new chapter in the history of the origin of man The type skull, which unfortunately is the only one known from that locality, is that of a five-year-old child, and though there seems little doubt that Dart was right in regarding it as an ape much nearer to man than either the chimpanzee or the gorilla, some European men of science still seem to believe that it is a variety of chimpanzee or a dwarf gorilla, in spite of the fact that the milk teeth are entirely different in structure from those of the living anthropoids, and closely similar to those of man

In 1936 I discovered, at Sterkfontein, much of an adult skull which I described as *Australopithecus transvaalensis* It is clearly allied to the Taungs ape, but there are few points in which a comparison can be made between the two, and I provisionally placed it in the same genus In the last two years almost continuous exploration has been going on at Sterkfontein, and many interesting further remains have been found, notices of some of which have been published in NATURE

Until this year, nothing was known of the lower jaw except a beautifully preserved 3rd molar We still do not know much of the mandible, but we now have a well-preserved 2nd premolar, much of what I regard as a female canine, and the incisor portion of the jaw of a young male, corresponding to a human boy of nine years, with the perfectly preserved crown of an unworn canine This canine is unlike that of any ape at present known, but there seems little doubt that it is rightly identified as that of the male *A. transvaalensis*, from the resemblance it bears in a number of respects to the canine, which I regard as the lower canine of the female. Though little more than the incisor portion of the symphysis is preserved, it shows the sockets of the incisors, and reveals the interesting fact that the lateral incisors are considerably larger than the central ones. The shape of the symphysis is so different from that of the Taungs ape that it seems advisable to place *A transvaalensis* in a distinct genus, for which the name *Plesianthropus* is proposed.

In June of this year a most important new discovery was made. A schoolboy, Gert Terblanche, found in an outcrop of bone breccia near the top of a hill, a couple of miles from the Sterkfontein caves, much of the skull and lower jaw of a new type of anthropoid. Not realizing the value of the find, he damaged the specimen considerably in hammering it out of the rock The palate with one molar tooth he gave to Mr Barlow at Sterkfontein, from whom I obtained it Recognizing that some of the teeth had recently been broken off, and that there must be other parts of the skull where the palate was found, I had to hunt up the schoolboy I went to his home two miles off and found that he was at school another two miles away, and his mother told me that he had four beautiful teeth with him I naturally went to the school, and found the boy with four of what are perhaps the most valuable teeth in the world in his trouser pocket He told me that there were more bits of the skull on the hillside. After school he took me to the place and I gathered every scrap I could find; and when these were later examined and cleaned and joined up, I found I had not only the nearly perfect palate with most of the teeth, but also practically the whole of the left side of the lower half of the skull and the nearly complete right lower jaw. The only missing parts

Fig 1

PALATAL VIEW OF SKULL OF *Paranthropus robustus* BROOM, ABOUT ½ NATURAL SIZE THE TEETH OF THE LEFT SIDE HAVE BEEN WEATHERED OFF, BUT ARE REPLACED IN WHAT MUST HAVE BEEN NEARLY THEIR ORIGINAL POSITION PART OF THE SOCKET OF LEFT m^3 IS PRESERVED of importance are the halves of two molars, the crown of the left 1st upper premolar and the crown of the right lower canine. Those I still hope to discover. As, however, we have impressions in the matrix of some of the missing teeth and parts, we know nearly the complete dentition

The skull is that of a large ape, larger than most male chimpanzees and nearly as large as most female gorillas, but it differs very greatly from both the living African anthropoids. Much of the palate is preserved in perfect condition The whole of the left side of the sphenoid bone is also preserved; while the zygomatic arch is nearly complete The glenoid cavity and the tympanic bone are in perfect preservation, and much of the mastoid region, and part of the occiput with a portion of the left condyle

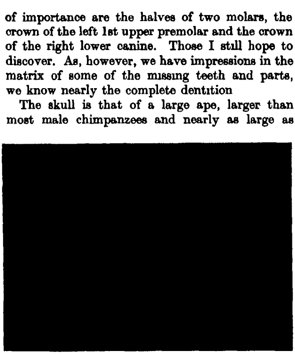

Fig 2

Side view of skull of *Paranthropus robustus* Broom. About ½ natural size.

The glenoid cavity and the relations to the tympanic bone are of exceptional interest. In the gorilla, the chimpanzee, the orang and the gibbon, the outer part of the tympanic is situated behind the posterior glenoid process In man, the tympanic is situated mainly below the glenoid process, and even at its outer part it forms the posterior non-articular part of the glenoid cavity In the new fossil ape, the condition of the glenoid and tympanic is almost exactly as in man, though the parts are very much larger.

The occipital condyle is in practically the same plane as the external auditory meatus and thus farther forward than in the gorilla and the chimpanzee; which appears to indicate that the ape walked somewhat more erect than the living anthropoids.

From the portion of the brain case preserved, I estimate the volume of the brain to have been about 600 c.c. The face is remarkably flat and much shorter than in the gorilla. A curious bony ridge runs down from the inner border of the large infraorbital foramen

The molar teeth, as will be seen from the illustrations, differ considerably in shape from those in *Plesianthropus transvaalensis*, and the 2nd premolar is about half as large again as in the Sterkfontein ape The upper canine had been lost before fossilization, but it must have been relatively remarkably small, and the incisors, of which we have much of the sockets preserved, were also relatively small. The palate is relatively short and broad, and owing to the small size of the incisors and canines the anterior part is narrowed, and the teeth are arranged more as in man than in any of the living anthropoids. The anterior two-thirds of the right mandible are satisfactorily preserved. The symphyseal region has been broken off behind the canine before fossilization and slightly displaced. The incisors which are lost have been relatively very small, and the lateral ones are scarcely larger than the central. The canine crown is lost, but the impression of its outer side is preserved in the matrix. It is quite a small tooth, and remarkably human in shape. It is clearly very unlike the canine of *Plesianthropus transvaalensis* The premolars have rounded crowns without any high well-developed cusps as in the living anthropoids, and are thus fairly similar to those of man, but about twice as large The 2nd premolar differs very markedly from that of *Plesianthropus transvaalensis*, and we may thus confidently place the new skull in a new genus and species.

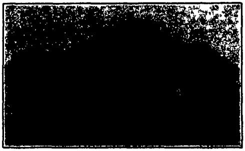

Fig 3

Occlusal view of molars, with roots of premolars, of right mandible of *Paranthropus robustus* Broom.

The deposit in which the skull was found is the floor of an old cave the walls of which have probably been weathered away thousands of years ago. We may therefore suspect that the deposit is very much older than that in the Sterkfontein caves, and this is confirmed by the associated fauna. It contains a jackal, a baboon, a horse and a hyrax, which are all of different species from those at Sterkfontein, and are most probably all older.

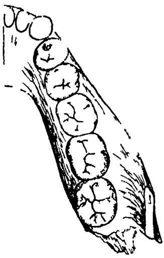

Fig 4

OCCLUSAL VIEW OF RIGHT MANDIBLE OF *Paranthropus robustus* BROOM ½ NATURAL SIZE THE PORTION OF THE JAW WITH CANINE AND INCISOR SOCKETS WAS DETACHED AND IS PLACED IN WHAT WAS PROBABLY ITS ACTUAL RELATIONSHIP

The skull may be referred to as the Kromdraai (pronounced Kromdry) skull and may be given the name *Paranthropus robustus*

It seems probable that the Sterkfontein skull is of Upper Pleistocene age the Kromdraai skull of Middle Pleistocene and the Taungs skull probably of Lower Pleistocene though of course more work will have to be done before the geological ages of any of these skulls can be determined with more than probability

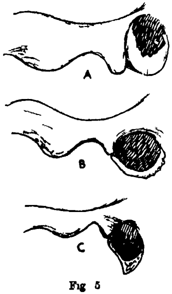

Fig 5

THE GLENOID AND THE EXTERNAL AUDITORY MEATUS IN (*A*) A LARGE MALE GORILLA (*B*) *Paranthropus robustus* AND (*C*) A LARGE KORANA MALE ½ NATURAL SIZE

Clearly during the Pleistocene there lived in South Africa a number of large brained anthropoids which resemble man in the shape of their premolars and in having relatively small canines and in having the glenoid region in at least some forms remarkably human in structure These Pleistocene apes are probably the modified descendants of forms that may have been widely distributed over Africa in Pliocene times and it is probably from one of the Pliocene members of the group that man arose

Quite certainly the conditions in Pleistocene times in South Africa were not unlike those of to day The apes lived on the plains and among the rocky krantzes At Taungs most probably the apes lived in the caves The associated animal remains seem to be the kitchen midden of *Australopithecus*

At Sterkfontein and Kromdraai the larger bones in the caves seem all to have been introduced by carnivorous animals and the small bones by owls Nearly every bone of the larger animals has been broken in pieces No perfect limb bone has been found and most teeth are detached from the jaws and many of the teeth have also been broken before fossilization

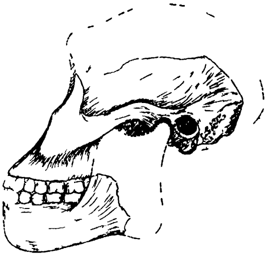

Fig 6

SIDE VIEW OF SKULL OF *Paranthropus robustus* BROOM ⅓ NATURAL SIZE RESTORED THE PARTS IN LINE ARE KNOWN

We have now a fairly good knowledge of the faunas associated with the apes We know about a dozen fossil mammals from the Taungs caves all extinct about thirty mammals from Sterkfontein nearly all extinct and we know about a dozen from Kromdraai all extinct except one—the living porcupine

Social and International Relations of Science

THE growing feeling among scientific workers that they have a definite part to play in the promotion of social well-being and in international affairs found expression in a discussion in NATURE of April 23. The outcome was a suggestion that the British Association should take up the matter, and the Council of the Association put forward a proposal for the establishment of a new Division for the Social and International Relations of Science. The proposal was agreed to by a meeting at Cambridge of the General Committee on August 17. We print below the memorandum prepared for the General Committee.

At the present time a strong feeling exists that the social relations of science demand close and objective study. The question has been dealt with recently in the Press and elsewhere. At an informal meeting of persons specially interested, it was stated that there is nothing in the constitution of the British Association to prevent the establishment of machinery within that organization for the purpose desired. A resolution was thereupon addressed from this meeting to the Council of the Association, inviting the Association to establish a special department which would consider the social and international relations of science, by means of inquiry, publication, and the holding of meetings not necessarily confined to the annual meetings of the Association.

International relations were specified in this resolution primarily because of the deep interest of the American Association for the Advancement of Science in the subject. Discussion is expected to take place between officers of the two Associations, during the present summer, on the best means for international co-operation.

The Council supported the proposal to establish an organization for these purposes within the Association. They appointed a Committee to formulate a scheme for the working of such an organization, to be presented to the General Committee at the Cambridge Meeting. It is thought that the organization should work on lines in some respects different from those of a Section, and should not bear that title. The term 'Division' is therefore recommended.

The purpose of the Division would be to further the objective study of the social relations of science. The problems with which it would deal would be concerned with the effects of advances in science on the well-being of the community, and, reciprocally, the effects of social conditions upon advances in science.

The Division would be worked by a Committee, nominated annually by the Council and appointed by the General Committee. The Council should have power to appoint additional members of the Committee during the year.

The Committee should embody the existing British Science Guild Committee of the Association, inasmuch as the Norman Lockyer, Alexander Pedler, and Radford Mather Lectures, now administered by that Committee, would appropriately come within the purview of the Division.

The President of the Association and the General Officers should be *ex-officio* members of the Committee. A chairman of the Committee should be appointed for a fixed period of office. A fixed proportion of the ordinary members of the Committee should retire annually (as in the case of the Council) and should not be eligible for immediate re-election.

The functions of the Committee would be:

(*a*) To arrange meetings of the Division both at the time and place of the Annual Meetings of the Association, and elsewhere at other times, as invited or otherwise arranged; to appoint speakers and to accept or reject communications offered to the Division.

(*b*) To furnish material for the information of the public.

(*c*) To co-ordinate work dealing with the social relations of science, both at home and abroad.

(*d*) To be prepared to act in a consultative capacity and to supply information, and to that end to establish relations with organizations and persons engaged in practical administration.

(For the furtherance of the above objects, the Committee, immediately upon the establishment of the Division, should issue an announcement thereof, together with a reasoned statement of its aims, to institutions and other organizations and individuals known or likely to be interested in its work.)

(*e*) To set up sub-committees for executive purposes, or for research, inquiry, or co-ordination. If any such sub-committee should require a grant of money for its work, the Committee should be empowered to apply for such grant to the General Committee or the Council in accordance with the usual procedure relating to research committees.

(*f*) To maintain close relations with the Sections of the Association and their Organizing

Committees In particular, there may be imagined subjects which two or more Sections might be disposed to recommend to the Division for discussion, in lieu of arranging joint meetings of the Sections. The Committee of the Division, on its part, should be enabled to invite the advice of the sectional organizations on all appropriate questions The Organizing Sectional Committees should be kept regularly informed of the activities of the Division

The Committee should meet regularly throughout the year, at intervals determined by itself, and in particular it should hold a meeting at or near the time of the joint meetings of Organizing Sectional Committees in January, in order to assure the relations with the Sections referred to above.

The Committee should report to the Council as and when necessary, and annually through the Council to the General Committee.

Logic and Probability in Physics*

By Dr. C. G. Darwin, F.R.S.

IN choosing a theme for my address I was in some difficulty The main subjects of present interest in physics, the nucleus of the atom, cosmic rays, and the phenomena at deep temperatures, are being dealt with in the discussions of our Section, so that they would be excluded even apart from the fact that I cannot speak on them with authority It would have been possible for me to choose a narrower subject, but I could not feel that this would have possessed the general interest that such an occasion demands, and so with some trepidation I am venturing on an even wider theme and am going to touch on the philosophy of our subject This is a dangerous thing to do for one who has never made more than the most superficial study of pure philosophy, but still I do not apologize for it, because it appears to me that recent scientific history has revealed a deep schism between the professional philosophers and the scientists, and this schism is worthy of examination

General philosophy claims to be the critical subject which lays down for all of us what we may be allowed to think, and yet it has played no part whatever in the great revolutions of human thought of the present century—those connected with relativity and the quantum theory It might have been expected that the scientists would have been constantly consulting the philosophers as to the legitimacy of their various speculations, but nothing of the kind has happened Since no one can dispense with some sort of metaphysic, each scientist has made one for himself, and no doubt they contain many crudities, but it would seem that a deep interest in metaphysic is a disadvantage rather than an advantage to the physicist—at least I have the impression that those of my friends who are most inclined to speculate on the ultimate things appear to be the ones whose scientific work is most hampered by doing so Now I propose to risk a similar indiscretion I want to embody in it the practical philosophy of a physicist, and I do not mean it as an attack on the pure philosophers, who are very reasonable people, only chargeable with the minor offence of not having made me want to read their books!

I had better begin by stating shortly the ideas I intend to discuss. There is a notable contrast between the way we think about things and the way we think we ought to think about them We have set up as an ideal form of reasoning the formal logic which has held the field since the days of Aristotle We rarely conform to this ideal, but instead we usually make use of arguments having no accurate axiomatic basis, which compel belief because of some large accumulation of favourable evidence I intend to develop the idea that the old logic was devised for a world that was thought to have hard outlines, and that, now that the new mechanics has shown that the outlines are not hard, the method of reasoning must be changed. The key to the modification has already long been in our hands in the principle of probability, but whereas in the past constant attempts were made to fit this into the old system, the new mechanics suggests the possibility of a different synthesis Though I hope this subject will be found interesting in itself, I would not have ventured to bring it forward if I had not also a very practical purpose in doing so, and that is to urge that our mathematical education both at school and university has been gravely deficient in that it has put all the emphasis on matters susceptible of rigorous proof, while it has very completely neglected the equally important subjects of statistics and probability. I shall enter into these matters at the end of my address.

---

* From the presidential address to Section A (Mathematical and Physical Sciences) of the British Association, delivered at Cambridge on August 19.

If we examine various examples of theories and why we believe in them, we conclude that an axiomatic basis, of the kind demanded for the operations of formal logic, is too narrow for the understanding of the physical world Something wider is needed. Now for more than a century there has been growing up the recognition that probability plays a part in much reasoning, and that there must exist a wider system of logic which has probability as one of its features. Attempts have been made, and are still being made, to bring probability back into the narrow fold of the old logic It appears to me that these attempts are hopeless, but before approaching the question directly I want to develop an analogy which seems to me important Like everyone else I *feel* the compelling power of the old logic, and I cannot *feel* how when we try to go beyond it we can get the same compulsive force. But on the other hand, I *know* of a case where our thoughts are driven in one direction by a force which seems to have the same psychological compulsion as does formal logic, and yet where the result is undoubtedly wrong

To anyone who has thought at all seriously about the world, or at any rate to anyone who has made an elementary study of mechanics, I suppose there is nothing more absolute than the law of causality By this I mean that the future is completely contained in the present Passing over obvious examples where this is true, like the path of a projectile or the orbit of a planet, we may take an extreme case where we might expect our faith in the principle would be most severely tried. Take the typical case of chanciness, the tossing of a coin We know that in a general way there is an even chance of heads or tails, even though we sometimes hear of gifted individuals with muscles so delicately adjusted that they can control the event. But in the ordinary way the tossing of a coin is complicated by being produced by a living organism, so let us simplify the problem by designing a catapult of some kind to project it. Which of us does not believe the coin would fall the same way every time if such a mechanism could be made with really complete precision ? When the machine fails to make it do so, we say it is because there may have been a speck of dirt in the lubricant or something like that. In other words, we do not feel that the fall of the coin is determined by chance, but we regard the uncertainty we observe as due to our ignorance of all the detailed causes. Ignorance is a confession of incompetence, and so we regard the existence of chance as a blemish in our otherwise admirable characters. This feeling goes very deep, since we are prevented by it from having the complete control of our surroundings that we somehow think should be our due. We start prejudiced against probability and in favour of causality.

So much for what we *feel* about causality , and about thirty years ago this feeling would have been regarded as a piece of inescapable reasoning, with the same kind of compelling power as a logical syllogism We still have the feeling, but now we know it is wrong, and what is more, we know that it is wrong for a reason we never thought of. To understand this oversight we must review the recent history of atomic theory.

[There follows a review of the history of the quantum theory with special reference to the way in which it disposes of the difficulty of causality]

The history of the quantum theory serves as an analogy to the deeper question of what is wrong with the old logical processes. Just as we used to feel the all-pervading compulsive force of causality, so we feel the all-pervading force of pure logic. Just as we felt that classical mechanics provided no room for anything beyond itself, so we feel that the old logic is the only admissible kind of reasoning We knew that certain things led to the Old Quantum Theory and obstinately refused to fit into mechanics, and we know that the principle of probability can cover many things outside the old logic. Many men tried to force the quantum into the classical system, and many are still trying to bring probability within the fold of the old logic I do not believe it can be done. This is not the occasion, nor have I the capacity, for a deep argument on the place of probability in logic, but one of the most convincing ways of seeing it may be found in the consideration of another branch of physical theory, the kinetic theory of gases.

The greatest contribution to the subject was that of Gibbs, who recognized that there had to be a big assumption somewhere and made it quite frankly and without attempt at justification. The works of Gibbs are not easy reading , in both his great works he attends to every detail with a particularity that is really rather tedious, whereas his basic ideas are thrown at the reader almost without explanation. The idea of a canonical ensemble is a really beautiful idea once you understand it, but where does it come from ? An ensemble is an idea which will be unfamiliar to many, so I had better explain it. We want to know something about the behaviour of a complicated system composed of a great many parts ; say we want to know the pressure of the gas in some vessel. Gibbs considers a very large number of possible states of motion of the set of molecules, which have some character in common such as their total energy, but which are otherwise unrelated. Though each specimen of the motions is quite independent of all the others, he looks at them all together; this explains the word *ensemble*—I do not know why he had to take a French word—and makes the assumption that the pressure of the gas is correctly given by the average of all the specimens. The actual gas in the vessel at any instant is one of the specimens, in its motion it passes into configurations corresponding to others, but only after a fantastically long time would it go through even a perceptible fraction of the whole ensemble. Gibbs is assuming that the behaviour of the actual gas will be determined by the average of the uncountable millions of specimens in the ensemble.

With the old mechanics all this involved ideas which for many readers were distinctly hard to accept. The principle of probability, embodied in the averaging over the ensemble, was frankly laid on top of the logical principles of Newtonian mechanics, and to anyone believing that probability would ultimately be brought down to the old logic the association was most repellent But we can now see that Gibbs was a prophet far ahead of his time—and indeed, to be frank, far ahead of his own knowledge—for the new mechanics accommodates the ensemble very much more easily than did the old The new mechanics has shown us that it is impossible to know how the individual molecules are moving, because when one undertakes an experiment to see, that experiment automatically alters the condition of the gas and so fails to tell what was wanted, the state of the molecules without the experiment.

In the old days one used to feel that the validity of Gibbs's idea would be spoilt by some skilful experimenter who would really observe the motions of the individual molecules and would therefore rule out the legitimacy of averaging over the *whole* ensemble, but we now know that there is no danger of this. The real gas in the vessel is not merely one specimen of the ensemble, unrecognizable only because of our clumsiness, it is itself the whole of the ensemble. We used to think of the gas as *either* in the state *A*, *or* in the state *B*, *or* in *C*, but according to the new physics we have to think of it as in *all* the states *A and B and C*. The distinction is typical of the change we must make in our habits of thought, and most of us resist this change strongly, for we find we can scarcely help asking: 'But which state was it really in?' As I have said, we used to be ashamed of ignorance, but we must now realize that *this* ignorance is one of the things that makes the world possible. The principle of probability, which used to be loosely superposed on the old logical principle, is now with the new mechanics fully united with it in a higher synthesis.

Before leaving Gibbs I would like to refer to one thing in his book, where I think he has not even yet come into his own He considers various types of ensemble of increasing generality. In the micro-canonical the members all have the same energy Now we never know the exact energy of the gas in a vessel, so that a better idea is the wider one of a gas at a given temperature which therefore has a certain range of admissible energies. This is represented by Gibbs's canonical ensemble, and it is the main one that he uses In both these the number of atoms in the ensemble is constant But in the last chapter of his book Gibbs introduces a still wider ensemble He calls the ones with a constant number of atoms *petits ensembes*, which I shall translate as petty ensembles, and regards them as parts of a grand ensemble in which the total number of atoms is not fixed. He uses the idea to some extent in connexion with semi-permeable membranes, but on the whole does not get far with it

As in much of Gibbs's work, it is the idea itself, rather than what he does with it, that is important This idea of the grand ensemble is not yet incorporated in the new physics. In the quantum theory we take a number of electrons and nuclei, and, allowing for their interactions, we construct something that is practically the canonical ensemble But we take fixed numbers of them—this is partly reflected in the technical process of using normalized wave-functions Now in an experiment dealing with a large number of particles we are never really sure exactly how many there are, and to assume this number is much like assuming a constant energy for them If the canonical ensemble is a better idea than the micro-canonical, then the grand ensemble is superior to the petty ensemble In the new mechanics nobody has yet succeeded in making anything of it, or has made any proposal how to do so, but I will venture the forecast that when some of our present difficulties in the quantum theory are cleared up, it will be found that we shall be using the grand ensemble with its indefinite number of atoms

Reverting to my main theme, what is the moral of all this? It is that the new physics has definitely shown that Nature has no sharp edges, and if there is a slight fuzziness inherent in absolutely all the facts of the world, then we must be wrong if we attempt to draw a picture in hard outline. In the old days it looked as if the world had hard outlines, and the old logic was the appropriate machinery for its discussion Things went wrong when it was found necessary to call in the help of the principle of probability; this appeared first as an alien, but there was hope in the old days that the alien might be naturalized. It has resisted the process and we now recognize that it cannot be assimilated, because it provides the necessary step to a wider reason, that of the new fuzzy world of the quantum theory, a world which is not contained in the old. How far it will be possible to make a full synthesis of the new and the old I do not know, but I like to think there is something in my analogy from the history of the quantum theory, and to suppose that we are still in the condition corresponding to the Old Quantum Theory, and that some day a real synthesis will be made like that of the New Quantum Theory, so that there will be only one thing in the world that has not indefinite outlines, and that will be a new reformed principle of reasoning

There may be a feeling among some that the very general suggestions I have been making are open to every sort of criticism Perhaps they are right; as I have said, it is part of my doctrine that the details of a physicist's philosophy do not matter much But whether it is wrong or right, my next point is one on which I do very much hope that there may be a consensus of agreement This is that the subject of probability ought to play an enormously greater part in our mathematical-physical education I do not merely mean that everyone should attend a course on the subject at the university, but that it should be made to permeate the whole of the mathematical and scientific teaching not only at the university but also at school To the best of my recollection, in my own education I first met the subject of probability at about thirteen years of age in connexion with the problems of drawing black and white balls out of bags, and my next encounter was not until the age of twenty-three, when I read a book—I think it was on the advice of Rutherford—on the kinetic theory of gases Things are better now, but mathematicians are still so interested in the study of rigorous proof, that all the emphasis goes against the study of probability.

This is not the place to describe a revised scheme of education I would only say that it is not special new courses that are needed, but rather a change in the spirit of our old courses. When a boy learns about the weighing machine, emphasize its sensitivity, and consider the length of time that must be taken for the weighing. When he has a problem on projectiles, make him consider the zone of danger and not merely the point of fall At a rather higher level, but still I should hope at school, introduce the idea of a distribution law; for example, in doing central orbits work out Rutherford's law of scattering Calculate the fluctuations of density of a gas, or the groupings in time of the scintillations of α-particles. All these things ought to be examples of a familiar train of thought, and not merely a highly specialized side-branch of mathematics first met at the university. It is the incorporation of probability in the other subjects on which I want to insist, but there will of course remain some higher aspects—things like least squares or significance tests—which are still to be treated in separate university courses Even these I should hope would come to be recognized as subjects of central interest and not, as they are at present, relegated to a remote corner of specialized study.

If these reforms are carried out. I shall hope that generations will grow up which have a facility that few of us at present possess in thinking about the world in the way which the quantum theory has shown to be the true one The inaccuracies and uncertainties of the world will be recognized as one of its essential features. Inaccuracy in the world will not be associated with inaccuracy of thought, and the result will be not only a more sensible view about the things of ordinary life, but ultimately, as I hope, a fuller and better understanding of the basis of natural philosophy.

Obituary Notices

Sir John Snell, G.B.E.

BY the death of Sir John Francis Cleverton Snell, the electrical profession has lost an inspiring leader, and all who knew him mourn the loss of a great-hearted and much-loved friend.

The son of Commander Snell, he was born in 1869, at Saltash, Cornwall, the county which produced Trevethick, Humphry Davy and other pioneers. Being unable to enter the Navy through defective eyesight, he decided to adopt an engineering career. He became a student of King's College, London (of which, in later years, he was elected a fellow), and after gaining valuable experience with Woodhouse and Rawson, and Crompton and Company (for whom he laid a complete system of underground mains in Stockholm), he became chief assistant to the late General Webber, and in 1893 became resident engineer to the Vestry of St. Pancras. From 1896 until 1906 he was borough electrical and tramways engineer of Sunderland, where he designed a new, and the main, power station and a complete system of electrical tramways.

In addition, Snell found time to publish in 1906 a work on the "Distribution of Electrical Energy", to be followed later by a complementary work on "Power House Design", which for many years were regarded as standard works.

All this time, Snell's virile brain envisaged a much wider sphere of activity, and as his advice on technical problems was sought with increasing frequency he took the plunge and established himself as a consultant in Westminster. His practice rapidly increased, and also his reputation as an expert witness, and as an authority on the rating of electricity undertakings. In 1910, he amalgamated his practice with that of Messrs. Preece and Cardew, the new firm being known as Preece, Cardew and Snell.

Perhaps Snell's outstanding achievement in these years was in connexion with the acquisition by the State of the telephone service He was the principal technical witness for the Crown in the arbitration proceedings, and was in the witness-box for thirteen days. His case was prepared with that meticulous care and accuracy which distinguished him throughout his career, and as a result, he was largely instrumental in saving the country more than £8,000,000

Snell received the honour of knighthood in 1914, and later, as a reward for further public services, he was created a G.B.E. in 1925. He was retained as electrical adviser to the Board of Trade on matters such as the regulations for the safety of the public Owing to the growing importance of electric supply as a public utility, the Government of the day passed the Electricity (Supply) Act, 1919, for the reorganization of the industry, and placed the control in the hands of an independent body of experts known as the Electricity Commission. Snell was persuaded to accept the office of chairman (though at a considerable financial loss to himself), a position which he adorned until his retirement in January last

In 1925, Snell was chief technical adviser to the Weir Committee, the recommendations of which were embodied in the Electricity (Supply) Act, 1926, which provided for the re-organization and co-ordination of electrical generation on national lines, under the direction of a new body, the Central Electricity Board, a function of which was to interconnect by means of the 'Grid' the most efficient power stations and close down the smaller and less efficient plants The generating side of the industry being thus placed on a soundly organized basis, he turned his attention to the reorganization of the distribution side, envisaging the reduction of more than six hundred separate undertakings, which had grown up in somewhat haphazard fashion, to a much smaller number, by means of amalgamation or acquisition on fair terms. He was a member of the McGowan Committee which reported its conclusions to the Government in 1936. The Government has announced its intention of promoting legislation to this end

The outstanding achievements of 'Snell's career may be summarized as (1) his work for the country in connexion with the acquisition of the telephones; (2) the reorganization of generation into one orderly whole and the establishment of the 'Grid'; (3) the unification of the frequency throughout the country to a standard of 50 cycles in place of various frequencies ranging from 25 to 100 cycles; (4) the encouragement of a standard of A C voltage of 400/230 which, though not yet universal, is making encouraging progress; and (5) the encouragement to electrical undertakers to take long views—especially with reference to rural electrification.

Sir John Snell was president of the Institution of Electrical Engineers in 1914–15, and was awarded the Faraday Medal in March last, in recognition of his distinguished services to electrical science: vice-president of the Institution of Civil Engineers in 1926–31 and only ill-health prevented his accepting the presidency: past-president of the Incorporated Municipal Electrical Association in 1902–3: past-president of the British Electrical and Allied Industries Research Association in 1928–29: president of Section G (Engineering) of the British Association in 1926 (Oxford meeting)

Though it will be obvious that Snell's opportunities for recreation were scanty, he was keenly interested in the petrological study of rocks, particularly those of igneous and metamorphic origin In late years he made a special study of the contact minerals associated with the aureole of metamorphism surrounding the Cornish granites. He was always a great bird lover, and in his younger days he used to tame various wild birds to come to the hand.

The present writer, who enjoyed his friendship for more than forty years, and who for a decade was in almost daily touch with him, would give the following impression of Sir John's character. He had the judicial mind to a marked degree In his conduct as chairman of conferences and inquiries, he was always dignified, always fair, and those to whom he had to announce an adverse decision never doubted his integrity and impartiality To all who came in contact with him, whatever their station in life, he showed a fine old-world courtesy

T P WILMSHURST.

Mr. E. M. Nelson

BY the death of Edward Milles Nelson on July 20, at the ripe age of eighty-seven years, a great microscopist has passed away He was the son of a doctor, and after a brief period of study at Corpus Christi College, Cambridge, he entered the service of a telegraph company and was for a time engaged in laying submarine cables along the coast of South America, and between the Shetlands and the mainland Even at this period, he was never so happy as when testing the performance and optical qualities of a telescope, sextant or other optical instrument

Nelson afterwards settled in London, and in 1876 joined the Quekett Microscopical Club, of which he later became president for three successive years (1893–95), and contributed a number of papers to its *Journal*. He now devoted himself more and more to work with the microscope, being much more interested in the theory, construction and use of the optical parts of the instrument than in the objects examined. He had an acute controversy with Abbe respecting the proper conditions for obtaining the best performance of microscope objectives of high numerical aperture. Abbe maintained that a small (pin-hole) stop in the substage condenser was the proper combination, whereas Nelson held that a large aplanatic cone is essential, and this was afterwards proved to be correct His views on this subject were contributed in a paper to the *Journal of the Quekett Microscopical Club* (4, Ser. 2, 116; 1890).

Nelson was also a fellow of the Royal Microscopical Society, to the *Journal* of which he communicated some two hundred papers and notes between 1881 and 1914 He was likewise president of this Society for three years (1897–99).

Possessed of very keen eyesight and unlimited patience, Nelson by his method of 'critical illumination' demonstrated many structural details previously unknown in diatoms and other microscopic forms of life, and in 1882 exhibited at the Royal Microscopical Society. Nobert's 19th band resolved for the first time in England He also devoted much time to photomicrography with conspicuous success, and contributed the fine series of photomicrographs which illustrate the 1891 edition of "Carpenter on the Microscope", edited by Dallinger.

Nelson was also interested in the telescope, upon which he had privately published a little book in 1893, and he aroused the interest of Col. Gifford in this instrument, who, guided by Nelson, computed apochromatic telescope object glasses with very perfect corrections. The designing of mathematical scales and rules and the calculation of mathematical tables, with special reference to optics, were other subjects at which he worked. Nelson was also interested in ancient stone circles and made a considerable study of them, resulting in the publication of a small book on the subject, "The Cult of the Circle Builders".

In private life, Nelson was deeply religious and an admirer of classical culture in its proper sphere. He will be greatly missed by microscopists, for he was always ready to place his unrivalled knowledge and technique at the disposal of all—and they were many—who sought his help. R. T Hewlett.

News and Views

Sir Albert Seward, F.R.S.

By the election of Sir Albert Seward as president of the British Association for the meeting to be held in Dundee next year, botany again assumes the presidential dignity after a comparatively short interval, since Prof F. O Bower was president of the Bristol meeting in 1930 Sir Albert's work and influence have been, and still are, very widespread in scientific research and in guiding the destinies of science and academic administration. For thirty years (1906–36), he held the chair of botany at Cambridge, which, since his retirement, is being filled by one of his former students, Prof. F. T. Brooks. For some years before Sir Albert's election to the chair at Cambridge, he had been fellow and tutor at Emmanuel College, and for sixteen years, University lecturer in botany; so his connexion with Cambridge has been a very long one. During 1915–36, he was Master of Downing College, and in 1924–26 Vice-Chancellor of the University. Thus has he been able to play a large part in academic administration at Cambridge for which his scientific attainments and personal qualities were admirably suited. He is a fluent speaker with an exceptional fund of sharp humour. Most of Sir Albert's scientific work has been associated with palæobotany, and his name is joined by botanists with those pioneers who were responsible for lifting botany from the stagnant condition in which it was in Great Britain several decades ago, to the very live condition in which it finds itself to-day.

Sir Albert's palæobotanical work has proved of inestimable value to present-day concepts of plant evolution and the distribution of plants in geological time. These researches have been published over a long period of years, and still continue. His more general works include the "Wealden Flora" and the "Jurassic Flora", both in the British Museum Catalogue series, and "Fossil Plants and Tests of Climate". Students of botany and geology have for long been indebted to him for his "Fossil Plants for Students of Botany and Geology" in four volumes, while his more recent book "Plant Life Through the Ages" is a pattern of conciseness and clarity of style. His particular scientific interest in recent years has been the study of plants in past geological ages with particular reference to their distribution over the world and the indications they give of climate in geological time. But he has always fostered the study of botany in all its aspects and not merely as regards his own special interest. In more general fields, Sir Albert's influence has been even more profound. He was president of the International Botanical Congress held at Cambridge in 1930; president of the Geological Society of London in 1930, and president of Section K (Botany) of the British Association in 1903 and again in 1929. He has served on the Council of the British Association and was one of the local secretaries for the very successful Cambridge meeting of 1904. He was a vice-president of the recent Cambridge meeting. Since 1934 he has been foreign secretary and a vice-president of the Royal Society. During his academic career, and since his retirement, his work has received well-merited recognition from many sources. He is honorary member of most national academies and societies and was awarded a Royal Medal of the Royal Society in 1925, the Wollaston Medal of the Geological Society in 1930 and the Darwin Medal of the Royal Society in 1934. His influence and advice have not passed with his resignation, for he is now a trustee of the British Museum and a member of the Advisory Council of the Committee of the Privy Council for Scientific and Industrial Research. With the British Association, he has visited Canada, Australia and South Africa, and is otherwise widely travelled. Sir Albert's election to the presidency of the British Association will be welcomed by all men of science, especially botanists and geologists.

Cambridge Meeting of the British Association

THE meeting of the British Association which has just closed will long be remembered by all who attended it. At the first meeting of the General Committee, it was agreed to form a Division for Social and International Relations of Science (see p 380), which may well prove a vital step in the history of the Association Lord Rayleigh's address was received with much enthusiasm, and a specially warm welcome was given to Sir J. J. Thomson, who moved a vote of thanks to the president for his address, and also to Dr. G. D Birkhoff, past president of the American Association for the Advancement of Science, who, as spokesman of the delegation from his Association, expressed his desire to see active co-operation between the British and American Associations in the cause of international friendship The customary announcement at the close of the inaugural meeting, made by Dr. O. J. R. Howarth in the absence of the general treasurer, Lord Stamp, of the number of tickets issued for the meeting, showed that the attendance, 2,795, while not a record, was highly satisfactory The services of broadcasting were utilized to bring the Association's activities before a wider audience in Great Britain and also in the United States. Prof Allan Ferguson broadcast an account of the opening meeting through the B B.C., while on August 19, Lord Rayleigh and Sir Richard Gregory were 'interviewed' before the microphone by Mr. Watson Davis, director of Science Service, and the 'interview' broadcast in America

THE setting at Cambridge for the meeting was of course ideal, and the University and individual colleges showed their traditional hospitality. In addition to the discussions and papers before the several sections, members had an opportunity of inspecting an exhibition of old and historic scientific instruments, which appropriately included apparatus used by Sir J. J. Thomson and by Lord Rutherford, of seeing demonstrations and exhibits of gold films produced by Prof. C S. Gibson and his collaborators, and other more 'sectional' exhibitions The officers of the Association who have been elected for 1939 are as follows : *President*, Sir Albert Seward ; *General Treasurer*, Prof. P. G. H. Boswell ; *General Secretaries*, Prof. F. T. Brooks and Prof Allan Ferguson , *New Members of Council*, R. W. Allan, Prof. F. E Fritsch, Sir Richard Gregory, Prof. C. Spearman and Dr. C R. Fay. Future places of meeting of the Association will be Dundee (1939), Newcastle-on-Tyne (1940), Belfast (1941) and Birmingham (1942).

Impressions of Cambridge

A CORRESPONDENT writes : "Cambridge is the best of all places for the British Association to meet. There was an air of activity and exhilaration throughout the week, and the organization was carried out with extraordinary smoothness There were almost too many receptions, dinners and garden parties ; perhaps one could wish for a little more time for those discussions behind the scenes which are the most valuable feature of these gatherings. The great novelty of the meeting was, of course, the formation of the Division for the Social and International Relations of Science It was astonishing and encouraging to find the project so enthusiastically received by the widest variety of scientific workers It has lit up many people's imaginations, and given them a chance to devote themselves intelligently to something which offers a hint of usefulness in an increasingly lunatic world. Perhaps the shadow of the world outside has never hung so menacingly over a scientific meeting , many there felt that all they cared for intellectually might have vanished before long. It was noticeable that the most eager supporters of the new Division were often those whose own research happened to be particularly 'pure'. Those who complained in private that the cobbler ought to stick to his last usually turned out to be engaged on semi-applied research. It is, for example, interesting that the more abstract kind of physicists tend to be far more socially interested than people busy with traditional chemistry."

"DARWIN'S was easily the most exciting presidential address, and a model which other sections might usefully study It had the great advantage that the intelligent layman could listen to it and not waste his time , and yet it also contained ideas enough to set professional scientists and philosophers arguing for weeks Childe's and Southwell's were also nice pieces of work, and Griffith Taylor's highly entertaining For pure science, Blackett's Saturday morning talk on cosmic rays was unsurpassed. The trouble is, one wants to go to so many lectures that are taking place simultaneously But still, an energetic person could have heard something from Wells, Bohr, Darwin, Keynes, Blackett, Shapley and Huxley—which is not such a bad bag for a week's holiday "

Art at the British Association

A COLLECTION of photographs taken by members of the scientific delegation from Great Britain to the Indian Science Congress Association's jubilee meeting in January of this year was exhibited in the reception room of the British Association at Cambridge. Some of the photographs were of scientific personalities, others of Indian scenes and inhabitants, whereas several gave beautiful impressions of certain well-known Indian buildings at night, flood-lit and illuminated. A very pleasing innovation at this year's meeting, too, was the exhibition of works of art by members of the Association, which demonstrated very clearly that genius is not confined to a single avenue of interest. Many outstanding men of science are known to be accomplished in one or other of the arts, especially music, but this exhibition must have proved a pleasant surprise to many. Well over a hundred examples were exhibited, the chief among them being oil and water colour paintings, though examples also of ware, metal-work and hand-printing and weaving were on view. The arrangement of the exhibition would have reflected credit on the Royal Academy itself. All three members of the Bragg family have clearly found the painter's palette a valuable means of utilizing the little leisure at their command. Sir William Bragg, president of the Royal Society, showed an attractive study of aloes, while landscapes were also exhibited by his son, Prof. W. L. Bragg, Cavendish professor of physics in the University of Cambridge, and by his daughter, Mrs. Carol

Major C. E. S. Phillips, secretary of the Royal Institution, and Mrs Phillips, are known by many to be artists of considerable taste. Between them they showed six of their many paintings, one of them being "On the Purbeck Hills", by Major Phillips, which was exhibited in this year's exhibition at the Royal Academy. A beautiful interior of the Cathedral Church of Christ, Oxford, was exhibited by Emily Vaughan Jenkins One of the most interesting exhibits was a portrait of a spinster by Joyce Gardiner. The slightly embittered and very grim expression made the portrait live, and the title "Frustration" made the picture itself. Three landscapes by the late Dr. William Bateson, president of the British Association in 1914, and two by Mrs. Bateson showed an obvious love of rugged scenery. Three very beautiful paintings executed by the late Lady Robertson during the meeting of the British Association in Canada in 1924 were exhibited by Sir Robert Robertson, formerly Government Chemist E. N. Willmer, lecturer in physiology in the University of Cambridge, is known to spend much of his holiday periods painting landscapes; here he showed three examples of what is clearly a successful and enchanting hobby. There is also a good portrait of Dr. F F. Blackman, emeritus reader in botany in the University of Cambridge, by one of his colleagues, G. E. Briggs. Another by Briggs—"Cineraria"—besides being a poem of colour, also brings out the plant physiologist in the painter. The wilting of the leaves and the florets is strikingly natural

Fossil Anthropoids in South Africa

Further discoveries of the fossilized remains of anthropoids in South Africa, which were announced on behalf of Dr. Robert Broom of the Transvaal Museum during the meeting at Cambridge of the British Association (see p 377 of this issue of Nature), constitute an addition of the first importance to the evidence relating to the early history of man and his precursors which has been accumulating in South Africa since the discovery of Rhodesian man in 1921 and the later discovery in 1925 by Prof. Raymond Dart of the Taungs skull, *Australopithecus africanus*. The doubts which had been expressed whether the latter might not be a young chimpanzee or gorilla, and not, as Prof Dart maintained, more closely related to the human stem than any fossil anthropoid then known, may be regarded as having been finally resolved by Dr. Broom's discovery of the Sterkfontein skull two years ago, to which he gave the name of *Australopithecus transvaalensis*, but for which his later discoveries now recorded lead him to adopt the significant nomenclature of *Plesianthropus*, expressing not only its generic difference from *Australopithecus*, but also its even closer relationship to man in the scale of development. This, however, does not close the tale of remarkable additions to our knowledge for which we are indebted to Dr. Broom. The story of how he rescued from the dangers of oblivion the fragments of still another and even more important relic, will command a tribute of admiration from all for his acumen and persistent energy in the pursuit of scientific discovery. He has been rewarded by the acquisition of what must be regarded as the most important piece of evidence now in existence relating to the evolution of man's ancestry. From fragmentary bones of the skull, the teeth, and the reconstruction of missing parts from the matrix, Dr. Broom has been able to reconstruct the Kromdraai skull, now classified as a new genus, *Paranthropus robustus*, and not merely coming closer in certain details to man than any previously known fossil anthropoid, but actually in line with man Equally important is Dr. Broom's conclusion as to its dating, for he is now able to say, subject to further geological investigation, that while *Australopithecus* is regarded as probably Lower Pleistocene, the Kromdraai skull is Middle, and the Sterkfontein skull Upper Pleistocene.

Russian Astronomers

The Polish journal *Acta Astronomica*, in its July issue, states that the following members of the staff of the Pulkovo Observatory have been imprisoned: I. A Balanovsky, N. I. Dneprovsky, B. P. Gerasimovič (director), P. I. Iaschnoff, B. W. Noumeroff (director of the Astronomical Institute at Leningrad, who is believed to have been shot), N. W. Zimmermann. The Editor of *Acta Astronomica* states that it would give him great pleasure to be able to refute this statement, a sentiment which we are sure scientific workers everywhere will echo.

Backward Peoples: a Proposal from Holland

The Netherlands Commissie voor Internationale Natuurbescherming (Netherlands Committee for the International Protection of Nature) has prepared through its recently constituted Committee for the Preservation of Primitive Races a general statement of the problem with special reference to the primitive peoples of the Dutch possessions in New Guinea. To this are added some suggestions as to how best to deal with the difficulties which will arise, or have already arisen, if and when peoples living in the stone age, who in some instances previously were not even aware of the existence of the white man, are suddenly brought into contact with the blessings (aeroplanes, motor-cars, radio) and the curses (alcohol and venereal disease) of Western civilization. A useful point is made, frequently overlooked, that an even greater danger than the white man in the matter of exploitation is the neighbouring native people of slightly higher culture which has assimilated or acquired some of the elements of white civilization. This statement of the problem is restrained, but well informed. Its details will be familiar to those who have studied the effects of contact between primitive and Western culture and the irreparable disasters which have followed upon such contacts in the last hundred years.

In putting forward certain suggestions as to how best to deal with the situation in areas in which the natives are at present virtually untouched, such as parts of New Guinea, the islands of New Britain, and the Congo, two principles are enunciated, one ethical, namely, that the ruling power must not restrict the natives' opportunities of ordered cultural development, the second that in the interests of science opportunity should be preserved for study of native cultures before they are hopelessly corrupted by unregulated contact with the worse elements in Western civilization Accepting the view that the interests of the native should be the first consideration, since commerce and industry may be trusted to look after themselves, the committee suggests that reserves should be created, not for the preservation of native tribes and cultures as museum pieces, but in order that these backward peoples may be led to develop gradually under supervision and strict regulation of contacts, cultural and other, in a slow but healthy upward progression, in which the elements of their own culture will be assimilated in higher forms of civilization. It will be seen that the ideal formulated by the Dutch Committee is sufficiently in accord with the views of those in Great Britain, who press for a scientific approach to the problem of the future of backward peoples, to warrant co-operation in the attainment of what is the common end. In any event, they will agree with the committee that the problem is urgent and immediate.

Jubilee of the American Mathematical Society

The fiftieth anniversary of the founding of the American Mathematical Society, which is being celebrated early in September at Columbia University, New York City, in connexion with the annual summer meeting of the Society, is unusual among jubilees of learned societies in that the principal founder of the organization in 1888 is serving as chairman of the committee in charge of the jubilee celebrations Prof. Thomas Scott Fiske, now emeritus professor of mathematics in Columbia University, took the initiative in bringing together six mathematicians fifty years ago to establish the New York Mathematical Society, having received his inspiration to do this from his attendance at meetings of the London Mathematical Society while a student at Cambridge the preceding year. Dr Fiske, as secretary of the young society, was indefatigable in his efforts to increase its membership, and succeeded so well that in 1891 the Society was strong enough to begin publication of the *Bulletin of the New York Mathematical Society*, which has been continued to the present time as the official organ of the Society, its name, of course, having been changed to correspond to the change in name of the Society to American Mathematical Society in 1894.

In 1900, the journal entitled *Transactions of the American Mathematical Society* was established by the Society for the publication of research papers. In the course of time the service of the Society to its membership in the promotion of mathematical research has come to include also an annual course of lectures on recent advances in some specific field of mathematics, and the publication of these in a series of Colloquium Publications, now numbering twenty-four volumes, the Josiah Willard Gibbs lectureship on applied mathematics, the maintenance of a library especially strong in relatively obscure journals, the award from time to time of several endowed prizes and the holding of ten or more meetings annually for the communication of approximately five hundred research papers. For many years Columbia University has provided office space for the Society, and more than half the regular meetings of the Society have been held in the University

The Centro Volpi di Elettrologia

Count Volpi di Misurata, whose name is associated with many important Italian electric companies, has decided, in the interests of science, to create an institution in Italy to promote the knowledge of, and research in, electrical science. He has presented the magnificent Vendramin-Calergi Palace in Venice to serve as a home for the new institution which will be known as the Centro Volpi di Elettrologia after its founder It is so arranged that it works in harmony with other existing Italian scientific societies. Its principal object is the improvement of electrical knowledge by means of new cultural exchanges between Italian and foreign scientists. Its main activities will be to publish a bulletin giving summaries of recent Italian researches, translated into various languages in different editions for distribution abroad It will also promote international congresses and meetings of men of science in the quiet Venetian palace so that they may advance electrical knowledge by exchanging ideas on specific scientific questions.

We have received a copy of the first bulletin of the Centro Volpi di Elettrologia in English. It illustrates briefly the activities of and the schemes initiated by the Centro Volpi It reports in the form of short abstracts all Italian publications dealing with electrical subjects. Great pains have been taken with the documentation of the bulletin. Each abstract is of such a size that it can be cut and gummed on an international card in accordance with the resolutions and recommendations of the World Congress of Documentation Later on, should some article appear which is important either on account of new ideas or results, or because it serves as a basis for cultural exchanges, an amplified summary will be given in addition to the usual notice. In this bulletin an interesting article on "Acoustical Research in Italy" is given The plans and sections of the new acoustic laboratory in the national electrotechnical institute 'G Ferraris' in Turin is described. At present the laboratory has in use four reverberating rooms and two sound-absorbing rooms. When completed it will have a sound-proof room for microphonic calibrations and acoustimetric experiments.

Safety in the Chemical Industry

IN 1928, the council of the Association of British Chemical Manufacturers decided to prepare and issue to its members for their guidance a set of model safety rules for use in chemical works These rules were based on the Factory and Workshop Act, the Chemical Works Regulations, the Electricity Regulations and similar statutory provisions, together with other precautions suggested from experience, and they represented the first attempt to draw up a comprehensive safety code for the chemical industry The first part of the model rules, consisting of the proposed safety rules in concise form, was completed and issued in provisional form early in 1929 Various amendments and additions have been suggested in the light of the experience gained during the past nine years, and this part has now been issued in final form covering the provisions of the new Factories Act, 1937 It is in the nature of an introduction to Part 2, the first section of which was also issued in 1929, and it is hoped to revise and complete it also for issue at an early date The model rules, Part 1 consist of eight sections, the first being a general section The following sections deal with rules for the design and operation of plant with fire and explosive risks, for plant involving risks from gas, vapour, fume or dust, for plant involving dangers from contact with corrosive or deleterious substances and for plant involving other risks The last three sections deal with fire protection, first aid, and with welfare The publication is a part of the services provided for by the Association for its members, but so much importance is attached to dissemination of safety information that the Association is prepared to supply copies to firms outside its own membership on special request

Malaria-Therapy by Means of Infected Mosquitos

TREATMENT of general paralysis of the insane by means of induced malaria, commenced in 1917 has been adopted everywhere In the early days of malaria therapy, the fever was induced by the injection of the infected blood of a malaria patient, and this is still occasionally done , but generally the fever is now transmitted through the bites of infected mosquitos This has been rendered possible by the establishment of a mosquito farm at the Horton Mental Hospital Full details respecting this mosquito farm', and of the methods employed for breeding, infecting and transmission are given in a recently issued report by Lieut Colonel J A Sinton ('A Report on the Provision and Distribution of Infective Material for the Practice of Malaria Therapy in England and Wales *Reports on Pub Health and Med Subjects*, No 84 London H M Stationery Office 6*d* net) At Horton, in a special insectary, an indigenous species of mosquito, *Anopheles maculipennis*, var *atroparvus*, is bred throughout the year, freshly hatched females are collected and are stored in cages in an outhouse, being allowed to feed on a rabbit at appropriate intervals When required for transmission work, the insects are placed in a special hot room for 48 hours, and are then allowed to feed upon a suitable patient with malaria in the wards of the hospital A special Madagascar strain of benign tertian malaria parasite, *P vivax*, is that used A batch of 100–200 mosquitos are allowed to feed on the selected case, the insects being placed in jars and applied to the thigh of the patient When most of the mosquitos seem to have fed, the jars are removed and the insects are then released into a storage cage, which is kept in a hot room maintained at about 75° F , and are fed every second day on a rabbit After 10 days or so, when parasites are found in the salivary glands of the insects, the mosquitos are ready for use for transmission , they remain active for about a month For the transmission to a patient for the cure , about 15–20 infected insects are placed in jars and are taken to the hospital where the patient is The mosquitos are then given an opportunity of biting by applying the gauze covered end of the feeding jar to the external surface of the patient s thigh

Mining and Fuel Technology at Sheffield

THE University of Sheffield s report on research work carried out in the Departments of Mining and Fuel Technology during the session 1936–37, recently published gives a particularly lucid summary of progress made in the work undertaken by those two Departments Within the confines of its twenty pages it is not possible to include a comprehensive account of every phase of the research, nor to publish many of the valuable results obtained Nevertheless it can be amplified by reference to the technical papers cited in the appendix or by direct appeal to the university authorities The Department of Mining has been concerned chiefly with the problem of provision in advance of ventilating schemes for projected workings, and it is hoped to publish tables from which it will be possible to calculate roadway sizes required to provide adequate ventilation under varying conditions Problems of deterioration in efficiency of high candle power electric lamps, resistance of different types of trailing cables to mechanical damage, influence of design and material on chain coal cutter picks and investigations into the nature and conditioning of washery water, have received careful consideration by the Department, and valuable data have been adduced in these connexions The Department of Fuel Technology has been concerned during the period with the compilation of a revised method of classification of coal with the view of ultimate definition of the relationship between compositions and properties of different coals This work has been facilitated by the discovery of differences in behaviour between the younger and older coals which afford a useful basis of classification of coals of varying geological age.

Earthquake of August 16

AN earthquake of 'destructive' intensity was recorded on seismographs in Great Britain in the early hours of Tuesday, August 16 The epicentre of the shock is calculated to be about 5,500 miles away, possibly in the plains of Central Asia A message from the seismological station at Hamburg, Germany, states that the primary waves arrived at $4^h\ 38^m\ 55^s$, and the secondary waves at $4^h\ 47^m\ 54^s$, giving the distance of the epicentre from Hamburg at 7,600 km. As the region of the supposed epicentre is sparsely populated, it will be some while before direct information is available

The Science Museum: Recent Acquisitions

A LARGE collection of astrolabes, portable sundials, clocks and other scientific instruments, mainly of the sixteenth and seventeenth centuries, has been presented to the Science Museum by Mr. W E. Miller and has now been placed on exhibition The astrolabes are particularly fine examples; they include a fifteenth-century specimen from Germany and a sixteenth-century Flemish instrument, probably by Arsenius, one of the leading makers of his era. Among the sundials are several unusually large and fine ivory tablet dials by well-known south German makers of the early seventeenth century, as well as an interesting series of pocket dials of various types, many of them indicating time on the old Italian system in which the day-and-night period was divided into twenty-four equal hours, starting from zero at sunset and counting from 1 up to 24 The clocks have small projections opposite the hour numbers on the dial, so that the time can be found by touch during the night.

The Night Sky in September

THE sun crosses the celestial equator at the autumnal equinox (or First Point of Libra) on September 23 at 17^h U T. The moon is full on September 9 at $20{\cdot}1^h$ and new on September 23 at $20{\cdot}6^h$. For a few days near full phase, the moon rises only 21–23 minutes later on successive evenings instead of the normal 50 minutes in these latitudes—hence the Harvest Moon. The moon occults two naked-eye stars during the month, namely: (1) δ Piscium (mag 4·6) on September 11, when its reappearance from behind the moon's disk, as seen from Greenwich, takes place at $22^h\ 40{\cdot}6^m$ U.T. at position angle 238° from the north point; (2) ε Tauri (mag. 3·6) on September 15, the disappearance taking place at $22^h\ 32{\cdot}2^m$ at 131° and the reappearance at $23^h\ 07{\cdot}5^m$ at 211°. The respective times and position angles as seen from Edinburgh are $22^h\ 35{\cdot}4^m$ (118°) and $23^h\ 18{\cdot}9^m$ (224°). Lunar conjunctions with the planets occur as follows: with Jupiter on September 8 at 7^h; with Saturn on September 12 at 8^h; with Mars on September 22 at 14^h and with Venus on September 27 at 9^h. Mars, a morning star difficult to see, is in conjunction with Mercury on September 4 at 20^h and September 16 at 15^h; on September 5, Mars is near the first magnitude star Regulus. Jupiter is a bright object rather low in the night sky and southing at about 22^h in mid-September. The various phenomena of the satellites may be followed with the aid of the tables and diagram given on pp. 616–617 of the *Nautical Almanac* for 1938. The four bright inner satellites, visible with binoculars, are most closely grouped near the planet at $22^h\ 15^m$ on September 1, 7 (all eastwards), 8, 10 (one satellite occulted), 17 (the same satellite again occulted by Jupiter), 18, 25 and 26 Saturn, which is now visible throughout the night, souths at about $1^h\ 30^m$ in the middle of the month. The diameter of the minor axis of the ring system is about 8″. At 22^h on September 15, Arcturus is setting in the north-west; Aldebaran is rising in the north-east, preceded by the beautiful cluster of the Pleiades.

Announcements

MR R. W. HAMILTON has been appointed to succeed Mr E. T. Richmond as director of the Palestine Department of Antiquities Mr. Hamilton has been acting director since the retirement of Mr Richmond a year ago, and joined the staff of the Department as inspector in 1931 after experience with the British School of Archæology in Palestine.

IN NATURE of May 7, p 823, concern was expressed over the geophysical observatory at Zi-Ka-Wei. A correspondent informs us that he has just received a parcel of seismograms from the observatory. Thus in spite of the troubled times around Shanghai, the observatory is apparently carrying on its work.

THE Rockefeller Foundation has offered and the London County Council has accepted the sum of £2,500 for the assistance of psychiatric research at the Maudsley Hospital

THE twenty-fifth French Congress of Medicine will be held at Marseilles under the presidency of Prof. Olmer on September 26–28 Further information can be obtained from Prof Roger, 66 Boulevard Notre-Dame, Marseilles.

THE second International Spa Federation Congress will be held in Berlin during the second half of September and will consist of five sections devoted respectively to the economic, legal, medical, and technical aspects, and tourism and propaganda. Further information can be obtained from Reichsfremdenverkehrsbund, Potzdamer Platz 1, Berlin.

WE have received a copy of "Spectrochemical Abstracts, 1933–1937", by F Twyman (London: Adam Hilger, Ltd., 3*s* 10*d*, including postage 4*s*). This is a 52-page bibliography with abstracts of 228 papers on spectro-chemical analysis which have appeared in the period stated The references to the literature are grouped in an author index, to which references are made in the subject-matter, which is conveniently divided into topics under materials. There is also a list of recent books on the subject. The work, which is bound in limp covers, will be welcomed in scientific and technical laboratories.

REFERRING to the letter by E V. Newnham entitled "Effects of Floods in East Norfolk", published in NATURE of August 6, p. 257, Dr. Margaret Jepps writes: "Late in July one still passed (at Horsey, Norfolk) suddenly from a green landscape in high summer dress to a wintry scene with bare hedges and leafless woods between the brown wastes where in places the frost yet appeared to lie, since there had been too little rain to wash away the salt left by the receding seas."

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 400.

Capture Cross-sections for 220 Kev. Neutrons

THE selectivities (in Z) observed in the activation of nuclei by capture of slow neutrons are explained by differences of the energy (E) of the lowest neutron resonance level in different nuclei · the contribution of one level to the capture cross-section for thermal neutrons is proportional to $1/E^2$, while the cross-section at resonance is proportional to $1/\sqrt{E}$, the measured values of E lie between 1 and 200 volts The application of the one-level formula[1,2] to the experimental results yields some evidence on the neutron width Γ_n and the radiation width Γ_r of the best-known resonance levels. Some experimental evidence on the total widths has also been obtained[3,4,5]

Little or no direct evidence exists concerning the distance of the neutron levels for the excitation energies given by the mass defect of the captured neutron. The kinetic energies for which slow neutrons are selectively captured should lie between 0 and the distance of the levels Statistical considerations seem to be scarcely applicable, since of course the lowest resonance energies are the easiest to observe and in the case of some nuclei the capture cross-section of which is very small and where no pronounced level has been found yet, the first resonance level for slow neutron capture may be situated rather high Bethe and Placzek[2] have suggested the study of neutron capture under special conditions : for a neutron source emitting a spectral band broad enough to cover several resonance levels and the lower energy limit of which is high compared with the level distance, they derive the cross-section formula

$$\sigma = \pi^2 ƛ^2 \cdot \frac{\Gamma_n \Gamma_r}{(\Gamma_n + \Gamma_r)D},$$

D being the averaged distance between levels and $ƛ$ the wave-length of the neutrons divided by 2π. This formula is obtained by summing the one-level formula over an interval containing many levels The factor $\frac{\Gamma_n \Gamma_r}{(\Gamma_n+\Gamma_r)D}$ tends to become 1 when $ƛ$ becomes comparable with the distances existing between single particles within the capturing nucleus, that is for neutron energies of some million electron volts ; for lower energies the factor would in any event be smaller than 1. On the basis of the nuclear compound model one should expect it to be of the same order of magnitude for nuclei of similar mass and for equal excitation energy.

Activations with high-energy neutron beams considered free of slow neutrons have already been carried through with D + D neutrons of some 2·5 Mev.[7] We made some measurements with a source of photo-neutrons produced by the γ-rays of thorium C″ in heavy water This source gives neutrons of an average energy of 220 Kev. which in consequence of the conservation of momentum are distributed on a 40 Kev.-wide band The source (5 c c. D_2O with the γ-ray source in the centre, suspended far away from diffusing walls) was surrounded by cylinders of the elements investigated. Only nuclei for which a neutron-capture period is known were resorted to ; the activities were measured by means of a Geiger-Muller counter which fitted inside the cylinders. In order to obtain the absolute cross-sections, the number of neutrons emitted by the source was determined after the method of Amaldi and Fermi[3,6] A determination of the thickness responsible for the emission of one half of the observed β-rays was also carried through. The following cross-sections were obtained :

	^{27}Al	^{51}V	^{55}Mn	^{58}Ni	^{63}Cu	^{75}As	Se	^{79}Br	^{81}Br	^{108}Pd
σ (in 10^{-26} cm^2)	8	9	9	< 9	≈ 9	83	< 3	160	< 30	250

	^{107}Ag	^{109}Ag	^{121}Sb	Te	^{127}I	^{138}Ba	^{164}Dy	W	^{197}Au	Tl
σ	300	460	110	< 10	175	< 2	< 70	26	230	≈ 10

The factor $\Gamma_n\Gamma_r/\{(\Gamma_n+\Gamma_r)D\}$ being equal to σ divided by $\pi^2ƛ^2 = 0\cdot 94 \times 10^{-22}$ cm^2, its values in 10^{-4} units are represented by approximately the same numbers.

The results show considerable variations even for neighbouring nuclei, the nuclei showing biggest cross-sections being identical with those showing big cross-sections for *slow* neutron capture A careful search was therefore carried through in order to make sure that the source does not produce slow neutrons, which might account for the observed selectivities in Z. Any influence of outside diffusing substances such as the floor could be excluded ; in order to avoid the slowing down of neutrons, the cylinders were never touched by hand during activation A process of slowing down by collisions in the heavy water could be ruled out, since additivity was observed when smaller amounts of heavy water were used instead of the total 5 c c. The influence of (unknown) γ-rays of meso-thorium producing slower neutrons could be excluded by neutron absorption measurements in silver, using a silver detector.

The observed differences in the capture cross-sections are, therefore, real unless we assume the existence of a hitherto unknown isomer (difficult to observe because its period is too long or too short) in each case of seemingly low cross-section.

The coincidence that the same compound nuclei which show pronounced resonance levels at very slow neutron energies, show the big values for $\frac{\Gamma_n\Gamma_r}{(\Gamma_n+\Gamma_r)D}$ observed here, would imply the fact that the average distance of levels at the excitation energy given by the mass defect of the neutron is especially low for these nuclei. The table shows also that the nuclei with big capture cross-sections have mostly odd proton numbers and even neutron numbers.

A detailed account of these results will appear soon in the *Journal de Physique* We are indebted to Dr G Placzek for many valuable discussions

Hyperfine Structure Perturbations in Iodine due to Nuclear Quadrupole Moment

MURAKAWA[1] has recently published a more extended multiplet classification of the lines of the first spark spectrum of iodine, which differs in a number of respects from that given by Lacroute[2] and used by me in analysing the hyperfine structures The line multiplets which have been arranged are in both cases similar, but the term allocations differ Since, however, Murakawa retains almost all the J values found by Lacroute, the hyperfine structure analysis is only affected in the very few cases where the proposed J values are not in agreement

The evidence from hyperfine structure strongly favours the classification of Murakawa For example the identification of the sp^6 levels removes the anomaly which was previously reported[3] for the interval factor of the term given by Lacroute as $(^4S)5d\ ^3D_2$ Also the hyperfine structures of the newly classified lines, where known, fit perfectly into the analysis now given Further, a number of minor difficulties encountered in a recent more detailed analysis of the hyperfine structures[4] are removed by the use of the new classification

From Murakawa s results the classifications are now known for a number of lines the hyperfine structures of which I have already measured From these, ten new interval factors have now been derived, the details of which will be given elsewhere A very exact analysis has been made from which it is evident that at least seven terms exhibit perturbation, the interval rule breaking down The frequency of this indicates that it must arise from the existence of a nuclear quadrupole moment However, the interaction energy for each perturbed level does *not* obey the $\cos^2$ law found to hold in other cases by Schüler[5] Instead a cubic law is necessary to account for the observations This can be written as

$$E = a_0 + \frac{a}{2}\ C + b\,C\,(C+1) + c\,C^2\,(C+1),$$

where

$$C = F(F+1) - I(I+1) - J(J+1)$$

The perturbation constants for the eight terms not obeying the interval rule are shown in the following table (The units are $\text{cm}^{-1} \times 10^{-3}$)

For terms with $J = 1$ the constant c is arbitrary and has no precise meaning since there are only three fine structure levels which can always be adjusted to fit an equation with three constants

The ratio of c to b is so high that the contribution of the cubic term becomes of great importance This cubic term appears to be too large to be accounted for by assuming it to be a second order term in the accepted theory of quadrupole moment perturbation

Term	a_0	a	b	c
$(^2D)\ 6s\ \ ^3D_2$	502	65 5	0 44	− 0 015
$(^2D)\ 6p\ \ ^3F_2$	345	41	0 19	+ 0 009
$(^2D)\ 6s\ \ D_2$	454	72	+ 0 11	− 0 012
$(^4S)\ 5s\ 5p^6\ ^3P_2$	1030	∽ 152	∽ + 0 2	—
$(^4S)\ 5s\ 5p^6\ ^3P_1$	600 5	176 1	+ 0 38	
$(^2D)\ 6p\ \ ^3D_1$	344 8	107 1	+ 0 72	
$(^2D)\ 6p\ \ I$	100 8	18 4	0 87	
$(^4S)\ 5d\ \ ^3D_1$	1 9 3	40 8	0 39	

If this is indeed the case then the constant c must involve some nuclear physical property other than electrical quadrupole moment There is strong evidence for assuming that the effect is due to a new phenomenon, namely nuclear *magnetic* quadrupole moment

A detailed report will appear elsewhere

Quantum Theory and Relativity

STARTING from the assumption that the possibilities of defining and measuring high relative impulses are limited in a new way, because of the nature of β ray forces (with participation of neutrinos) and because of the appearance of explosion showers in the high energy collisions, an attempt is made to solve the convergence difficulties of quantum theory The proposed solution is based on a new kind of algebra of quantum states and observables, and on the assumption of the existence of a new kind of indetermination arising from the interaction of high energy particles with the measuring apparatus

In every measurement there is always a part of the measuring apparatus which constitutes the reference frame So for example, in the γ ray microscope, it is the diaphragm which limits the angular aperture and produces the characteristic diffraction phenomena Considering all observables referred to such a reference frame, we assume that the new phenomena responsible for the supplementary indeterminacy in the region of high relative impulses have a universal character that is, they appear in the collision of all kinds of particles The assumptions referring to this indetermination can be formulated in the following manner Let us consider an assembly of particles in a *Hohlraum*, and adopt as basic states the eigenstates of the momenta From the point of view of the present quantum theory, the number of states in the interval $(p, p + dp)$ is given asymptotically by $dz = \frac{8\pi}{c^3} V p^2\, dp$ In this formula we introduce a converging factor $G(p)$ in such a way that the number of new quantum states which can be defined relatively to the *Hohlraum* is: $dz^1 = \frac{8\pi}{c^3} V.G(p)\,p^2\,dp$, where $G(p) \sim 1$ if $p < b$, and $G(p) \to 0$ if $p \to \infty$, and $b = h/r_0$ is a critical value of the impulse. It means that a Lorentz observer has no possibility of distinguishing between states belonging to an assembly of $n(p) = G^1(p)$ neighbouring states. (A discussion of the measure of p by means of the Compton effect shows that the possibilities offered by this measure are not incompatible with the existence of the indeterminacy here examined.) For example, if a particle with $p > b$ produces showers by collision with the walls, the usual eigenstates become energetically connected and consequently indistinguishable. Considering the correlation between the quantum states and the cells of volume h^3 in the phase-space, we can say that it is impossible to distinguish experimentally elements of an assembly of $n(p)$ neighbouring cells, and thus it is necessary to consider such an assembly as constituting a unique quantum cell in the new theory. We assume, therefore, that the observables, impulse p_x and co-ordinate x, relative to a reference frame individualized by the measuring apparatus, satisfy the commutation relation of the type.

$$\Delta p_x\,\Delta x \gtrsim h \cdot f(p_x),$$

where $f(p_x) \sim 1$ if $|p_x| < b$ and $f(p_x) \to \infty$ if $|p_x| \to \infty$

Recently I have shown that it is possible to build an example of representatives of these new states and observables satisfying the following rules: the number of states for a unit impulse interval has a maximum for $p \sim b$; the total number of states is finite, the representatives of the states corresponding to the impulse-operator are not orthogonal; the *orthogonality is approximately satisfied only for* eigen values $p < b$.

In order to satisfy the claim of relativistic invariance, it is possible to substitute systematically for the impulses the modulus of the difference between two 4-vectors p_ν referred to an initial and a final state respectively. The consideration of the reference frame individualized by the measuring apparatus in this formulation of the theory gives results of great importance.

The most important consequences of the modified algebra of states and observables will be discussed in detail elsewhere. Let us confine ourselves to some remarks regarding the possible origin of Heisenberg's explosion-showers. According to the present quantum theory, the simultaneous production of many particles in a single quantum process is very improbable because it corresponds to a high-order process of the perturbation theory. In a first order transition the selection rules, derived in the case of photons from the orthogonality and peculiar properties of the eigenfunctions of a harmonic oscillator, forbid transitions with emission and absorption of more than one photon. The representatives of the new quantum states corresponding to $p > b$ are not orthogonal and differ sensibly from the usual representatives. Therefore the first order process with simultaneous emission of many particles becomes probable, with the same order of probability as the single particle transition.

A more detailed discussion shows that in the barycentric *frame of two colliding* particles the impulses of secondaries have their probable values $\sim b$ because the great majority of quantum states is condensed in the region $p \sim b$. In another reference frame, in which the barycentre is moving with an ultra-relativistic velocity, nearly all secondaries are projected, with $p \gg b$, within a small solid angle (as in the hard showers of Bothe). The existence of a lower limit of measurable lengths follows also from the assumption discussed above.

Indeterminacy and Electron Spin

SINCE a dipole of magnetic moment M in a magnetic field of intensity H has a potential energy $-M.H$, two free electrons in magnetized iron with magnetic axes respectively parallel and anti-parallel to the direction of magnetization should differ in potential energy by $Heh/2\pi mc$, where H is the effective field intensity acting on a free electron in the iron. It may be of some interest to see whether this difference in energy could be detected in an ideal experiment, for example, by a splitting under magnetization of the photo-electric threshold of iron, or whether the quantum indeterminacy prevents the resolution, as Bohr has shown it must in a Stern-Gerlach experiment on a beam of free electrons[1].

Let the field be assumed parallel to a boundary of the iron. At the photo-electric threshold those electrons will just escape which reach the boundary with a velocity v normal to the surface, the work function being given by

$$W = \tfrac{1}{2} mv^2$$

The path of these electrons in the iron will be an arc in a plane normal to the direction of magnetization and having a radius given by

$$\rho = mvc/He.$$

They must therefore have received the kinetic energy W at some point on a semi-circle in the iron, and their initial angular position is thus determined within the angle π. Canonically conjugate with the angular co-ordinate is the angular momentum given by

$$mv\rho = m^2v^2c/eH = W \cdot 2mc/eH.$$

The indeterminacy in the angular co-ordinate being π, we have

$$\pi \cdot \Delta(mv\rho) > h$$

whence

$$\Delta W > Heh/2\pi mc.$$

But this is just the difference in energy that was to be resolved, and the resolution is thus impossible.

If the direction of magnetization is normal to the boundary, the conclusion is the same. The argument in this case resembles that for the Stern-Gerlach experiment in that it depends on the divergence equation of the magnetic field.

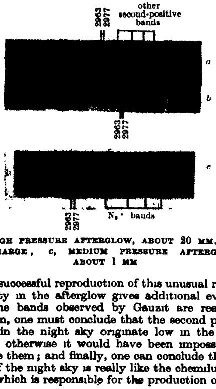
Existence of the Bands 2963, 2977 in Night Sky Spectra

THE list of wave-lengths in the light of the night sky, which was reported by Gauzit[1] two years ago, includes the two second positive bands of nitrogen 2963 and 2977 with an intensity ratio of 2 to 1 Since those bands lie in the region of the great Hartley absorption band of ozone, the reality of those observations could readily be open to question The importance of additional evidence concerning this problem is understood when it is pointed out that the shortest auroral radiation which has been reported is the second positive band at 3110

If the 2963 band has really been observed by Gauzit, it would mean that this radiation originates lower in the atmosphere than most auroral displays. Recent afterglow pictures, taken at very high pressures, show these two bands and the remaining band of the sequence, with about the same relative intensity as that reported by Gauzit, and not at all like the intensity distribution in the electrical discharge in which 2977 is at least as intense as 2963. These are shown in the accompanying figure



a, HIGH PRESSURE AFTERGLOW, ABOUT 20 MM., *b*, DISCHARGE, *c*, MEDIUM PRESSURE AFTERGLOW, ABOUT 1 MM

The successful reproduction of this unusual relative intensity in the afterglow gives additional evidence that the bands observed by Gauzit are real. In addition, one must conclude that the second positive bands in the night sky originate low in the atmosphere, otherwise it would have been impossible to observe them; and finally, one can conclude that the light of the night sky is really like the chemiluminescence which is responsible for the production of these afterglows.

An Anomalous Change in the Electric Resistance of Iron-Silicon Alloys with a Longitudinal Magnetic Field at Various Temperatures

THE electric resistance of Fe-Si alloys was measured in a longitudinal magnetic field at various temperatures. The specimens were annealed at 1000° C. for one hour and re-annealed at 850° for one hour after setting them on the measuring apparatus.

The relation between the changes in resistance and temperatures at a constant field of 1,500 oersteds for 1·66 per cent and 9·43 per cent silicon alloys was obtained as shown in the following table.

1·66 per cent silicon		9·43 per cent silicon	
t (° C.)	$R/R \times 10^2$	t (° C.)	$R/R \times 10^2$
− 195	− 0·055	− 195	− 0·135
− 95	− 0·025	− 95	− 0·133
10	0·010	10	− 0·103
100	0·040	100	− 0·076
201	0·075	200	− 0·059
300	0·075	300	− 0·024
402	0·070	401	− 0·011
505	0·065	499	0·001
592	0·048	599	− 0·010
703	0·019	643	− 0·050
745	− 0·022	650	− 0·080
776	− 0·116	660	− 0·142
789	− 0·177	670	− 0·029
801	− 0·020	690	− 0·010
820	0·000	720	− 0·003

From this table, we see that the resistance decreases with the longitudinal magnetic field at temperatures other than in the vicinity of the Curie point, which phenomenon was not observed in the alloys of Ni-Cu[1], Ni-Co[2] and Fe-Ni[3] previously investigated. The decrease of resistance in solid solution alloys is a very interesting fact, which has not heretofore been observed by investigators. This phenomenon has been also observed in Fe-Al alloys. The complete report of the present investigation will shortly be made in the Science Reports of the Tôhoku Imperial University.

In conclusion, I wish to express my cordial thanks to Prof K Honda, president of the Tôhoku Imperial University, and to Prof H Masumoto, under whose kind guidance the present investigation has been carried out

Gamma to Alpha Transformation in Iron Alloyed with Palladium

THE gamma to alpha transformation of iron is of fundamental importance in the heat treatment of steels. The face-centred-cubic gamma form, stable at high temperatures, transforms so rapidly to the body-centred-cubic alpha form below 906° C. that it cannot be preserved by quenching Various alloying elements stabilize the gamma phase so that it may be obtained at room temperature as a stable or metastable form

Carbon is of predominating importance among these elements. It is soluble to a considerable extent in gamma iron, being dissolved interstitially, but is almost insoluble in alpha iron. Consequently, austenite (gamma iron containing dissolved carbon) tends to decompose below the transformation temperature into alpha iron plus a carbon-rich phase which is cementite, Fe_3C, or graphite. For low carbon contents, this reaction takes place too rapidly to follow, but above 0·7 weight per cent carbon (3·2 atomic per cent), it may be arrested by a sufficiently rapid quench. Quenched samples are found to consist of austenite plus martensite.

Martensite is considered to be an intermediate phase in the decomposition of austenite into alpha iron plus cementite at sub-critical temperatures It is body-centred, like alpha iron, but the cubic symmetry is distorted into tetragonal by lengthening of the c axis. The c/a ratio decreases linearly with decreasing carbon content If this trend is extrapolated, c/a would apparently be close to one at zero per cent carbon. Thus, martensite resembles a supersaturated solution of carbon in alpha iron, with the symmetry distorted by the carbon.

This suggests that with a suitable quench the first step in the decomposition of austenite is a rearrangement of atoms into a body-centred form. Further annealing will result in the expulsion of carbon in a carbon-rich phase. Although a large number of papers have been written on this subject, the mechanism of this transformation is still disputed

In an X-ray examination of the iron-palladium system, we found an intermediate stage in the decomposition of the gamma form which resembles martensite in several respects.

Palladium, which is miscible in all proportions with gamma iron, is only slightly soluble in alpha iron There is a wide two-phase region between alpha and gamma extending at low temperatures from 1 or 2 atomic per cent palladium to about 42 atomic per cent.

However, samples containing 5·5, 10 and 20 atomic per cent palladium showed only a single body-centred-cubic phase when quenched from the gamma range The lattice constants of this phase increased linearly with the palladium content, as shown in the accompanying table. Since all the lattice constants are greater than that of a saturated solution of palladium in alpha iron, it is assumed that the palladium is in supersaturated solution.

LATTICE CONSTANTS OF SUPERSATURATED SOLUTIONS OF PALLADIUM IN ALPHA IRON

Atomic per cent palladium	Lattice constant
0	2·86
Saturated at 740° C	2·87
5·5	2·89
10·0	2·91
20·0	2·96

Hence, under the quenching conditions, the decomposition of the gamma phase takes place in at least two steps. First, the atoms rearrange themselves into a body-centred form, then palladium is precipitated out in a face-centred palladium-rich phase.

The resemblance to martensite is obvious, but there are several differences which should be noted First, palladium is dissolved in a substitutional rather than an interstitial solid solution. Second, only one phase is present in the quenched sample, while in the iron-carbon system austenite accompanies martensite. Third, the intermediate phase is cubic, rather than tetragonal.

The quench by which the intermediate phase is obtained need not be drastic. Lines are fairly sharp, except for those near back-reflection, which are diffuse. Two other samples, containing 34·4 and 39·5 atomic per cent palladium, respectively, retained the gamma phase on quenching.

We expect to publish our work on the complete iron-palladium system later. We are indebted to Dr A B. Greninger and Mr. A. R. Troiano for illuminating discussions of the martensite problem.

Adsorption Potentials and Ageing Liquids

Messrs Craxford and Gatty and Lord Rothschild[1] have recently commented on our letter[2] on "oil-potentials", that is, the E M F of cells of, for example, the type ·

Calomel electrode	Electrolyte BA in water C_1	Oil' (= water-immiscible organic liquid)	Electrolyte BA in water C_2	Calomel electrode

Everyone must admit that the processes in such an 'oil-cell' are very complicated. If we wish to understand them, we have to idealize in some way or other (which, of course, means a loss of exactness). Previous investigators have tried the ideal "Partition equilibrium at the interfaces, steady diffusion between them". Finding this theory inconsistent, we have suggested that another ideal, "Adsorption equilibrium, negligible diffusion", will in certain systems give a better qualitative and even quantitative agreement with facts

Now Craxford, Gatty and Rothschild state that there must still be a certain diffusion of ions through the interfaces. This we have not denied. But we cannot understand their argument: "the cells examined by Ehrensvärd and Sillén take up definite potentials", they say, but if "the interphase contains a boundary across which no charged particle can pass", "it has no definite potential of its own" Now a palmitic acid monolayer between water and air should suit the above description, as it is very hard to imagine a diffusion of ions from water to air. But it still has a definite potential of its own according to work of Rideal, Schulmann[3], *et al.*

Craxford, Gatty and Rothschild quote the well known modernized form of Henderson's integra formula for diffusion potentials[4] and also give a few reasons why it is useless in this case. There are other reasons for this too. For example, we have to do not only with the two ions of the salt, but also with the ions of water and whatever charged particles may transport electricity inside the oil. The transport number, t_i, for each kind of charged particle will therefore be a hopelessly complicated function of the concentrations and mobilities of all sorts of particles present. Moreover, this function should be integrated

Instead of leaving the question at that point, we have tried to find a practical method of attacking the problem. Especially we hope that the adsorption point of view will prove useful for understanding rapidly changing biological systems, where diffusion will have very little time to develop.

One complication we met in our experiments at first greatly confused us. There is a remarkable difference between the E.M.F's of a certain oil-cell if the organic liquid is freshy distilled, and on the other hand if it has been kept in a glass bottle for some time after the last distillation (of course, the cells are prepared in exactly the same way). After a few hours or days in the glass bottle, the process of 'ageing' seems to be terminated After that, the oil will give the same E.M F. in a certain cell whenever it is taken from the bottle A difference is also found between newly prepared and aged oil-mixtures, for example, of nitrobenzene and benzene Dr. Y. Björnståhl, Uppsala, has told us that he has found similar ageing effects with the magneto-optic properties of nitrobenzene and some other liquids.

What has happened inside the oil? Dr F. C. Frank, of Oxford (at present of Berlin), has suggested to us that the ions of the glass may have slowly dissolved into it. We are rather inclined to think that it is a question of molecular re-association We have read the long discussion of Baker, Smits[5] and others without being much wiser. If anyone could give us a hint, we should be grateful for any communication, public or private, as we have very little time left for a special investigation of this question. So far we have mostly studied 'old' liquids, as giving more constant values.

Our work is still proceeding. By experiments on the short-circuiting of oil-cells and cataphoresis of oil droplets, we are now investigating the diffusion rate and the surface charge of the interfaces. Until this work is completed we intend to publish no more about oil-potentials. But we shall be very glad to have personal communication with Messrs Craxford and Gatty and Lord Rothschild.

Mode of Action of Visual Purple

FOR the chemical theory of excitation of nerve cells, the following observations as to how the retinal rods are stimulated by the substance visual purple would seem to be of general interest Their understanding requires knowledge of the fact that after a preceding period of adaptation to sunlight the size of the electrical response of the eye to a constant test light reproduces the curve of regeneration of visual purple (see, for example, [1,2,3]). When the quantity of visual purple, obtainable from an eye after increasingly longer periods of dark adaptation, increases, the size of the electrical response (its *b*-wave) likewise increases owing—one would have thought—directly to the larger amount of cell stimulant available.

Actually, however, parallel measurements of visual purple densities and size of the electrical response in dark-adapted excised frogs' eyes under strictly identical conditions show that, after 5–10 minutes of adaptation to the moderately strong monochromatic stimuli from a spectral source, the electrical response may be greatly reduced without any parallel diminution of the concentration of visual purple. With test lights from the short wave-lengths 0·500–0·430 μ, and adapting lights 0·450 and 0·580 or 0·560 μ, it is found that the long wave-lengths may cause a reduction of the electrical response by some 40–50 per cent and that, contrary to expectation, the short adapting wave-lengths have a much smaller effect on the response to the test light, sometimes even causing it to increase[4] The total quantity of visual purple obtained from eyes in which the electrical response has been reduced by 1/3–1/4 by adaptation (digitonin extracts tested photo electrically) is neither influenced by the adapting wave-length used, nor is it reduced compared with the amount of visual purple of completely dark-adapted control eyes Our technique of measuring the density of visual purple of single retinas gives averages identical to within 7 per cent Therefore less than 7 per cent of the total visual purple is *active* in mediating maximal electrical responses in dark-adapted eyes The rest is a store of photosensitive material which is *inactive* from the point of view of excitation of the cell. However, this store must be large in order to enable the eye to react maximally[1,2,3]

DIAGRAM ILLUSTRATING OUTER LIMB OF ROD WITH ACTIVE STIMULATING VISUAL PURPLE (FILLED CIRCLES) AND INACTIVE NON-STIMULATING STORE OF VISUAL PURPLE INSIDE THE CELL

These facts are simply accounted for on the hypothesis (see the tentative scheme of the accompanying figure) that the active visual purple is active because of its particular manner of distribution, say, at the surface of the outer limb of the rod cell, but that a high concentration of the non-stimulating store of inactive material inside the cell is necessary for keeping up the charge at the surface Illumination may then be assumed to lead to a depolarization of the surface spreading electrotonically and giving rise to the *b*-wave of the electrical response of the retina

Synthesis of Growth Factors by *Rhizobium trifolii*

A STUDY of the growth factor requirements of *Rhizobium trifolii* has indicated that, under suitable conditions, the organisms are able to synthesize all the organic substances essential for growth from a synthetic carbohydrate - mineral salts medium of known composition. Although various extracts of plants and micro-organisms contain a heat-stable factor *stimulative* to growth, it is not required for successful continuous transfer of the organism in synthetic media. A base medium, claimed by Allison and Hoover[1] to be incapable of supporting continued growth of the nodule organism in the absence of extracts of *Azotobacter* or other substances (termed 'coenzyme *R*'), was found to be satisfactory after adjusting the oxidation-reduction potential and adding iron. Although the growth was not profuse in comparison with media which contain plant extracts, continuous transfer was possible

Further experimentation indicated that continuous transfer of *Rhizobium trifolii* in the purified base medium is dependent upon a highly active factor, synthesized by the growing culture and transferred in sufficient amount with a loop inoculum (0·005 ml.) to enable initiation of growth in the new medium Inoculations made with cells removed from the medium in which they had grown, and washed free of the metabolic products, caused little or no growth in the synthetic modified medium, whereas those not so treated grew well This separation of the cells from their essential factor can be accomplished by aseptic centrifugation of a fluid culture or by mere suspension of a small amount of growth from an agar slope in fresh medium Addition of so little as 0·01 per cent filtrate from a culture of *Rhizobium* (grown in the synthetic medium) or the autolysate of a culture permits 'washed' inocula to grow normally.

From various chemical and biological properties, to be described in detail elsewhere, two components of the *Rhizobium* factor have been identified as vitamin B_1 (thiamin) and riboflavin, which occur in the culture autolysates as heat-labile complexes. A method developed by West and Wilson[2] for the determination of vitamin B_1 has indicated that *Rhizobium trifolii* synthesizes 19·6 micrograms of vitamin B_1 per gm., an amount closely approximating that found in yeasts. Moreover, analyses for riboflavin likewise reveal a high content (0·3 microgram per milligram) of this vitamin. Although these substances are more active in combination, either one alone is capable of replacing the activity of the culture filtrate. Both thiamin and flavin, but especially the latter, have a very narrow range of activity; slight increases in concentration beyond the optimum result in lessened stimulation.

As previously pointed out by Laird and West[3], when inocula carrying metabolic products from the previous culture are employed, only a slight stimulation of growth is to be observed in the presence of thiamin. Later studies have shown the same to be true of riboflavin. In view of the recent report by Nilsson *et al.*[4] concerning stimulation of *Rhizobium* by thiamin, it was considered desirable to summarize the data obtained in these laboratories concerning the role of the B vitamins and other growth factors in the nutrition of the nodule bacteria.

Inhibition of Adventitious Bud Initiation in Hypocotyls of Flax by Indole-3-Acetic Acid and Flax Extract

Hypocotyls of intact flax plants (*Linum usitatissimum* L) rarely develop buds. If decapitated, the young hypocotyl initiates adventitious buds some of which develop into flowering shoots[1]. The result is the same if both the cotyledonary buds and the epicotyl are removed, but the cotyledons are allowed to remain. Hypocotyls of plants with cotyledons and the young epicotyl enclosed in a plaster cast remain budless. Segments of hypocotyls[2] and of internodes occasionally initiate buds. These findings suggested that bud initiation is under hormonal control which is disturbed by partial or complete isolation

Since each hypocotyledonary bud is initiated by division of a single epidermal cell[3] without immediately precedent enlargement, these findings suggested flax for study of the influence of its auxins and of indole-3-acetic acid upon the sequence of the cellular events which initiates an hypocotyledonary bud in flax.

Ether extracts of upper portions of plants severed in the hypocotyl were mixed in equal parts by weight with lanolin and applied daily for a week to cut surfaces of hypocotyls. Hypocotyls, cut and (*a*) treated and (*b*) not treated with lanolin, served as controls. Concurrently hypocotyls were treated with applications of indole-3-acetic acid in lanolin in concentrations ranging from 3 to 0·000056 per cent The flax extract significantly decreased both rate and frequency of bud initiation. Indole-3-acetic acid in concentrations ranging from $1·7 \times 10^{-2}$ to $7·5 \times 10^{-4}$ molar completely inhibited bud initiation but induced apical tumours, while the other concentrations, ranging from $3·7 \times 10^{-4}$ to $2·7 \times 10^{-6}$ molar, retarded and diminished it with progressively decreasing tumour formation Because of variability of material and growing conditions we have not been able to determine the end-point of deleterious effect for indole-3-acetic acid, or whether the lowest concentrations used ($5·5 \times 10^{-6}$ and $2·7 \times 10^{-6}$ molar) favour bud initiation as reported by Greenleaf[4], Beal[5] and Goldberg[6] for high concentrations when applied to tobacco, lily and cabbage.

Our findings add inhibition of hypocotyledonary bud formation to the long list of secondary effects produced in plants by native auxins (autoauxins) and by indole-3-acetic acid (one of the heteroauxins). Since in flax this bud formation is initiated by cell divisions which are not immediately preceded by cell enlargement, the results suggest that a cell-division substance (possibly a complex of substances) is a constituent of the causal complex which brings about these bud-initiating cell divisions. Probably these or other cell-division substances play their part in initiation and maintenance of the other meristems. Laibach's[7] term 'meristins' is suggested for this type of cytomerisone[8], which appears distinct from traumatin[9] and other wound hormones.

Went[10,11] has advanced a hypothesis of specific growth substances additional to auxins. In terms of this hypothesis the results here reported, in conjunction with those of others, indicate that auxin gradients influence meristins in such manner that the latter become effective in regions of relatively high auxin concentrations. In addition to influencing the transport and activity of meristins, auxins, through their influence on cell metabolism, also are factors in the production of cell-division substances. If it should develop that the substance (or substance complex) which initiates the cell divisions of a bud meristem and of its products (growing point and leaf primordia) is not only a cell division substance but also specifically a bud forming substance then it should be designated blastocaline to distinguish it from Went s rhizocaline[11], which forms roots If a specific meristin is involved in leaf bud and another in flower bud initiation, then a more specific term will have to be used for each

Conceivably the substances which specifically affect or effect the basic growth events of cells—increase in protoplasm cell size, cell number and cell complexity—are regulated in each plant by other specific substances in such manner that the various kinds of cells, tissues and organs of the plant are initiated and developed If this proves to be the situation, then the division substance indicated by our experiments cannot be designated blastocaline Probably internal factors other than specific chemical agents are also decisive factors in conditioning the kind, place, moment intensity and duration of the basic growth events of cells in such manner that the specific cells tissues and organs of each plant are initiated and developed

A Simple Conversion of *Trans*-Dehydro-Androsterone into Pregnane Derivatives

ABOUT a year ago, we published a method whereby it was possible to carry out a practically quantitative addition of acetylene to *trans* dehydro androsterone[1] We have in the meantime ascertained that the thereby easily obtained 17 ethinyl 3 *trans*,17 dioxy androstene (5), [*A*], in glacial acetic acid in the presence of acetic anhydride and mercuric oxide together with the boro fluoride ether catalyst[2] readily adds on acetic acid to the triple bond and gives rise to 20-acetoxy 3 *trans* 17 dioxy pregnadiene (5, 20), [*B*], m p 175–177° (corr); CH-determinations agree with $C_{23}H_{34}O_4$ The 3 monoacetate of [*A*] also adds on acetic acid with the formation of 3 *trans*, 20-diacetoxy 17 oxy pregnadiene-(5,20), [*C*], m p 191–192° (corr), CH determinations agree with $C_{25}H_{36}O_5$

By alkaline hydrolysis of [*B*] or [*C*] 3 *trans*,17 dioxy pregnen (5) one (20) is formed in good yield m p 275–277° (corr) $[\alpha]_D -78°$ (dioxan), CH determinations agree with $C_{21}H_{32}O_3$, oxime m p 245–247° (corr), CH and N determinations agree with $C_{21}H_{33}O_3N$ 3 monoacetate prepared by treatment with acetic anhydride and pyridine in the cold, m p 270–272° (corr) CH determinations agree with $C_{23}H_{34}O_4$

Further conversion products of these new compounds specially the preparation of 17 oxy progesterone and certain compounds in the corticosterone series[3] will be described later

Use of Amino Acids containing Deuterium to follow Protein Production in the Organism

WHEN α amino acids are heated to 100–170° with heavy water and strong acids or bases, heavy hydrogen (D) is introduced in a stable or practically stable position in the amino acid molecule[1, 2] The position into which D is introduced seems to be the C–H linkage at the α C atom and further into the ring of some of the aromatic and the heterocyclic amino acids

It was suggested[2] that amino acids prepared in this way could be used to follow the fate of amino acids in the organism The following experiment was made A rat starved for 48 hours, was given a food consisting of equal parts of dried milk whole rye flour and butter For every gram of protein was added 0 5 gm casein hydrolysate containing heavy hydrogen (dry and practically free from inorganic ions) This food was given for three days In all 3 5 gm protein and 1 75 gm hydrolysate was eaten by the rat Then the animal was killed (weight 150 gm) and single organs dried and extracted with acetone and petrol ether The casein hydrolysate used was prepared by heating 3 gm casein with 14 c c 50 per cent deuterium and 3 c c sulphuric acid (conc) in a sealed pyrex tube to 170° for 24 hours Sulphuric acid was removed quantitatively the water distilled off and the residue dissolved in ordinary water and dried again twice to remove the non stable deuterium By complete ignition this hydrolysate would give water containing 6 per cent D_2O The combined food protein and hydrolysate would give an amino acid mixture yielding water containing 2 per cent D_2O Assuming that only the *l* series of amino acids could be used by the organism for building up protein (the hydrolysate being a racemic mixture of both series), the concentration of D_2O formed by ignition of newly formed protein would be at most 1 per cent, and in reality somewhat lower on account of the differences as regards the relative amounts of the amino-acids in the food and the organs of the rat.

On determining the D_2O content of combustion water from liver protein, 0·1 per cent D_2O was found, which means that at least 10 per cent of the liver protein present after the experiment is newly formed from the food absorbed in the course of the three days of experimental feeding. In the muscle the concentration of deuterium was less, indicating that about 2·5 per cent of the protein was newly formed.

The water distilled off from the organs showed a D_2O concentration of 30 mgm. per cent, which shows that most of the ingested protein has been broken down in the organism. This experiment supports the well-known view that the liver functions as a protein depot[3], but experiments have to be done under varied conditions before definitive conclusions can be drawn

Chemical Studies on the Adreno-Genital Syndrome

IN a recent issue of the *Journal of Biological Chemistry* we published a paper[1] entitled "Chemical Studies on the Adreno-Genital Syndrome. (1) The isolation of 3(α)-hydroxyetiocholane-17-one, 3(β)-hydroxyetioallocholane-17-one (isoandrosterone), and a new triol from the urine of a woman with an adrenal tumor".

We wish to take this early opportunity of pointing out that the word 'hyperplasia' should be substituted for the word 'tumor' in this title. The mistake arose as a result of a slight misunderstanding in our correspondence with Mr L. R Broster, of the Charing Cross Hospital, who very kindly supplied us with the urine upon which these researches were carried out. We wish to add that this unfortunate misunderstanding arose entirely from an oversight on our part, and was in no way the fault of Mr Broster.

Points from Foregoing Letters

A TABLE giving the capture cross-section for 220 Kev. electrons, by various elements, is submitted by Dr. H von Halban, jun , and Dr. L Kowarski It shows that the nuclei with big capture cross-sections have mostly odd proton numbers and even neutron numbers.

Seven out of ten interval factors, calculated by Dr. S. Tolansky from the hyperfine structure of the iodine spark spectrum, show perturbations which indicate the existence of a nuclear quadrupole moment The interaction energy for each perturbed level necessitates a cubic law to account for the observed values.

Prof. G. Wataghin makes an attempt to solve the convergence difficulties of the quantum theory and to explain the explosion-showers, starting from the assumption that our ability to measure high relative impulses is limited in a new way. A new algebra of states and observables which corresponds to a supplementary indetermination (due to β-ray forces, neutrinos, showers) by the high-energy collisions is discussed.

Prof. R. T. Cox and Prof. F. E Myers consider that the quantum indeterminacy would prevent the observation of the difference in potential energy between the two free electrons in magnetized iron, which have magnetic axes respectively parallel and anti-parallel to the direction of magnetization

Prof. J Kaplan gives laboratory evidence supporting the reality of the observation by Gauzit of the second positive bands of nitrogen, 2963, 2977, in the light of the night sky Observation of three low wave-lengths is presented as additional evidence for a low origin of the light of the night sky.

X-ray study of the structure of iron-palladium systems shows, according to Dr. R. Hultgren and C. A. Zapffe, that the change from the gamma to the alpha form on cooling takes place in at least two steps : first the atoms rearrange themselves into a body-centred form, then palladium is precipitated out in a face-centred palladium-rich phase.

G. Ehrensvärd and L G Sillén discuss further their hypothesis that potential differences at oil-water interfaces are mostly determined by a state of adsorption equilibrium and negligible diffusion ; they point out, incidentally, that a change in potential difference may be observed between freshly distilled and old organic liquids, which may be due to molecular re-association

From the fact that the electrical response in dark-adapted frog's eyes may be greatly reduced without a parallel diminution of the visual purple pigment, Prof R Granit, T. Holmberg and M. Zewi conclude that the retinal rods contain a store of visual purple, only the surface part of which appears to be active at a given time.

Vitamin B (thiamin) and riboflavin are found by P M West and Prof. P W Wilson to be two components synthesized by growing cultures of *Rhizobium trifolii*, and necessary to it, if it is to be continuously transferred in synthetic media.

Prof. G. K. K Link and Virginia Eggers add one more to the long list of secondary effects of indole-3-acetic acid on plants in reporting that, in concentrations of $1 \cdot 7 \times 10^{-3}$ to $2 \cdot 7 \times 10^{-6}$ molar, this substance inhibits, retards or diminishes initiation of adventitious buds in decapitated hypocotyls of flax. These buds are initiated by division of a single epidermal cell without immediately precedent cell enlargement. It is concluded that the native auxin of flax and also indole-3-acetic acid are effective through influencing a cell-division substance or substance complex, which is designated meristin.

An easy conversion of *trans*-dehydro-androsterone into pregnane derivatives is described by Prof. L. Ruzicka and H. F. Meldahl.

By feeding casein hydrolysate, containing heavy hydrogen atoms, for three days to a rat, and determining the proportion of heavy hydrogen atoms in various organs at the end of that period, H. H. Ussing finds indications that about 2·5 per cent of the protein of the muscle and at least ten per cent of the liver protein was newly formed.

Research Items

Cultural Change in the Assam Hills

Mr Tarar Chandra Das, in the course of investigations carried out in 1931, 1932 and 1934, has made a study of certain cultural changes observed among small tribes in the hills surrounding the valley of Manipur, more particularly of the Chirus, included by some in the Naga group, by others among the Old Kuki (*Anthropos*, 32, 1937) Chiru economic life is based on agriculture, hunting being practised on one occasion only in the year, while fishing, or rather fish taking is merely a by product of irrigation of the paddy fields Trading is not practised as an occupation, but only as a method of disposing of surplus products, excepting only when betel leaves, obtained by exchange from the Kabuis, are sold as a means of raising money for the hut tax Two methods of cultivation are practised, *jhumming* in forest land on the slopes of the neighbouring hills, and by irrigation The latter is possible only on the land at the foot of the hills, and is evidently a recent introduction This is indicated by various features of Chiru economic, social and religious life The people have realized the advantages of this form of cultivation, and are gradually migrating towards the edge of the valley The Chirus are essentially a hill cultivation people The size of their villages is determined by the amount of *jhumming* land available, and increase of population, or even internal friction, readily lead to the founding of new villages The periodical religious rites and ceremonies, which take place on stated occasions in each month throughout the year, are all associated with *jhum* cultivation They are public festivities in which the whole village participates, but the religious festivals associated with wet cultivation in the irrigated fields are few and are entirely a family matter The hill village consists of families, each of which cultivates a patch in the *jhum* land This land belongs to the village, and though a man has a right to his patch when cleared, it is the usufruct only, enduring until the patch is exhausted and a fresh patch has to be cleared The wet cultivation fields, on the other hand, are rented from the Government or a landlord, they belong to the family and may be disposed of by sale, mortgage, or otherwise at such a price as the holder may think fit

Porifera of Krusadai Island

In a report by Dr M Burton, under the title of 'Porifera of Krusadai Island" (*Bull Madras Museum* Supplement to the Littoral Fauna of Krusadai Island in the Gulf of Manaar N S —Natural History Section, Vol 1, No 2, Pt 4, 1937), many species are included, as explained in an appendix, which were not collected in the Gulf of Manaar It is to be regretted that the substance of this important appendix, presumably compiled by the Madras Museum, and containing details of localities of occurrence, and colour in life of species, so far as known, was not included in the body of the report Frequent allusions in the latter to "colour in life", for example, are apparently derived wholly from other sources, and at times in disagreement with that recorded for the material concerned. The scheme of classification is based on the later system of Dendy, with certain modifications, hence, the Hexactinellida being unrepresented with 76 of the 89 species recorded in the report, placed under the order Tetraxonida The remaining 13 species are Keratosa, and seven others, as stated in the appendix, are omitted from the report Under the suborder Astrosclerophora, with 21 species, representing 16 genera, *Ecionema bacillifera* (Carter) is regarded as covering nine other species from the Indo Pacific region, with a table showing details of their differences Under the suborder Sigmatosclerophora, which is not defined, 55 species are recorded, representing 26 genera and 3 families Of the latter, the Desmacidonidæ contains 22 species, the Axinellidæ, though undefined, containing 18 species, and here including the genus *Halichondria* with one species, *H glabrata* Keller The Keratosa appear, through some error, under their two suborders as Dendrokeratida and Dendrokeratina respectively in place of the Dictyokeratida for the former—signifying, that is to say, the dictyal or net like character of the skeleton as compared with its dendritic tendency in the other case But whichever termination of the group name is used, the same in such a case should be retained for both In the second group, a sponge of doubtful position, without skeleton, is referred to the genus *Hexadella* of Topsent

Dermatophyte Fungi

The second fascicle of *Mycopathologia* (1, fasc 2 den Haag Dr W Junk June 1938) a new journal devoted to fungus parasites of man and the higher animals, includes several papers on skin diseases P Negroni describes in detail the cultural and microscopic characteristics of *Actinomyces discofoliatus*, which is concerned in human actinomycosis and lachrymal concretions A new species of *Trichophyton*, named *T immergens*, had been isolated by S Milochevitch, who describes its clinical manifestations, its pathogenicity geographical distribution, and other characters The disease can spread amongst human beings, and is also contracted from cattle It usually attacks bare skin, but can also disfigure the beard The fungus *Oidium albicans* is often associated with superficial diseases of human beings, R Ciferri, P Redaelli, and C Cavallero provide a very detailed summary of the taxonomic position and mycological characters of this species which should contribute materially to its more correct diagnosis It is somewhat surprising, but also sufficiently gratifying, that dermatophyte fungi are not very widespread in Great Britain but the exact results published from time to time in *Mycopathologia* should make the recognition and cure of such attacks as do occur a matter of exact science

Data of Seismology from the Argentine

A most interesting and informative publication has just been received from the Astronomical Observatory of the National University of La Plata in the Argentine Republic It is the "Resultados Sismometricos" for the years 1932, 1933 and 1934, and was published in 1937 at the observatory In it are given readings of the station's seismograms, including component, phase, time of arrival, period, amplitude in mm and absolute amplitude of ground movement, notes on the phases and notes on the character of the *P* wave and the estimated epicentre. Further, there are short notes on most of the seismograms, a list is given of the number of shocks recorded at the observatory month by month, and there is a geographical index of the epicentres of the shocks. The station is equipped with six instruments: a Mainka 450 kgm. arranged to register east-west movements, a similar instrument to register the north-south movements, a Vicentini 105 kgm., with free period 2·4 sec. and amplification 275 to register east-west movement, a similar instrument to register north-south movement, a Vicentini seismograph of 54 kgm. to register vertical displacement, and a Wiechert 80 kgm. to register vertical displacement. Since in the southern hemisphere there are very few seismological stations at all, and in the southern part of South America south of lat. 30° there are only six such stations in more than half a million square miles, these data will be very valuable.

Air Flow at Surfaces

No. 1803 of Reports and Memoranda of the Aeronautics Research Committee (H.M. Stationery Office. 5*s*. 6*d*.) contains a description of a new method devised by Dr. H. C. H. Townend of the National Physical Laboratory for studying the boundary layer flow of air along solid surfaces. If the surface has the end of an electrode flush with it and an electric spark is made to pass to it from a second electrode a short distance from it, the ions along the path of the spark persist for a short time, and if the air is moving parallel to the surface they are carried along with it. If a second spark passes, it follows the path already ionized which has drifted down stream, and so on for successive sparks. As seen or photographed from the side, the successive spark paths give the amount of drift of ions parallel to the surface in the interval between successive sparks, and therefore the velocity at different distances from the surface. For laminar flow the results found by the new method agree with those given by more elaborate methods, but for turbulent flow rather smaller velocities than the older methods.

Isotopic Lead

In a mass-spectrograph study of the isotopes of twelve samples of common lead, A. O. Nier (*J. Amer. Chem. Soc.*, **60**, 1571; 1938) shows that the relative abundances of the isotopes 204, 206, 207, 208 vary considerably in spite of a nearly constant atomic weight. Those samples which contained relatively more 206 also contained more 207 and 208. A tentative explanation for the variations is found if some of the samples are considered to be 'uncontaminated' lead, and the others to be this with the addition of approximately equal quantities of uranium and thorium leads. As the minerals from which the lead was obtained are essentially free from thorium and uranium, such contamination probably occurred before the mineral was formed. A recent attempt has been made to use the constancy of the atomic weight of ordinary lead (and the alleged isotopic constancy) to prove that this lead cannot be a concentration from granitic or basaltic rocks or their respective magmas, but must have its origin in some deeper source in the earth. The present work invalidates this conclusion; it is not inconsistent with the view that ore lead is related to ordinary igneous rocks, provided that the Th/U ratio in such rocks is taken as 4·0 rather than 1·6 to 2·4, as previously assumed. Reasons are given for supposing that the isotopic variations found are not present in the primeval lead itself, and that they are not due to isotopic separation, although it is emphasized that the theory put forward is tentative. A search for the isotopes 203, 205, 209 and 210 showed that, if these exist at all, they must occur with much lower abundance than was at one time supposed.

Rank Correlation

The problem of comparing two different rankings of the same set of persons is of some importance in psychology, and Prof. C. Spearman's coefficient of rank correlation is well known. An alternative method of measuring rank correlation is proposed by M. G. Kendall (*Biometrika*, **30**, 81; 1938), in terms of a new coefficient for which some advantages are claimed. Both coefficients are easy to calculate, and have distributions which tend to normality for a large population, but the distribution of the new coefficient is surprisingly close to normality even for a small population, and its standard error is known for the case where all possible rankings occur equally frequently. The distribution of the old coefficient is not known, but it appears to present some peculiarities, which will be discussed in a further communication to be published shortly. Finally, it is claimed that the new coefficient has a natural and logical significance.

Distribution of Stars in the Zone −40° to −52°

Dr. J. Jackson has recently published a paper entitled "Distribution of Stars in the Cape Astrographic Zone, −40° to −52°" (*Mon. Not. Roy. Astro. Soc.*, **98**, 7; May 1938) in which there is a very full discussion of the distribution of more than 40,000 stars. This zone has been photographed four times with overlapping series of plates, two series being taken round about 1900 with relatively short exposures, the fourth series being taken in 1923–28 for the determination of proper motions in conjunction with the most suitable of the earlier plates. There has been close co-operation with Harvard Observatory in the determination of spectral types, and the spectra of 38,713 stars in the zone were classified by Miss Cannon. Fifteen tables are given in the paper, and these deal with a multitude of subjects, amongst which may be mentioned the number of stars of each spectral type arranged according to galactic latitude and apparent photographic magnitude, separation of stars into dwarfs and giants by means of counts of stars according to magnitude, mean colour indices according to apparent photographic magnitude, percentage of stars in different ranges of proper motions, etc. Table XV shows the density distribution according to spectral type, and it has been computed from assumed absolute photographic magnitudes for stars in the main sequence. Although the table has been extended as far as type G0, the results have little meaning at this stage because many of the stars included do not belong to the main sequence. This table is very interesting, showing the great difference in the number of stars of different spectral type. There is a clear falling off of density in the groups of apparently bright stars, and it is suggested that the effect may not be real but may be due to the presence of distant giant stars in these groups.

Grain Structure of Sand Dunes and its Relation to their Water Content

By Major R. A. Bagnold, Imperial College of Science and Technology

THE stratification of wind accumulated sand beds is well known, and the evidence of it can often be seen on the vertical faces of sand pits Beadnell[1] has shown that the laminar structure of fresh non cohesive dune sand can also be observed, if the dry dune is soaked with water to allow a vertical face to be exposed without collapse The strata he thus exposed dipped at the angle of repose of sand, which experiments show to lie between 30½° and 35½° to the horizontal[2] In this case the succeeding layers have been formed by sand which, having been driven over the surface of the dune, has come to rest temporarily sheltered on the upper part of the slope, and has accumulated there, increasing the angle of the slope until shear occurs An avalanche then takes place down the slope from top to bottom (Fig 1) Fresh sand deposits formed in this way are characterized by their loose packing and by their extreme softness I have called[3] such a mode of deposition encroachment'

Another type of deposition occurs on a smooth sand surface over which sand is being driven by the wind, when, for various reasons previously discussed[3], more grains come to rest on the surface than are picked up from it In this case, which I have called accretion', the packing of the grains is very close and orderly, and the structure is peculiarly firm under normally applied pressure The layers here run parallel to the surface exposed to the wind (The accretion structure very probably corresponds to that of wind packed' snow) If a dune has advanced and grown bigger at the same time, both kinds of structure, encroachment and accretion, are present (Fig 2) This accounts for the alternate patches of firm and yielding sand found on desert dune surfaces

Fig 1

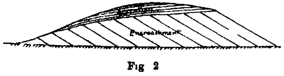

Fig 2

I have recently investigated the structure of a series of desert dunes, during an expedition carried out with the aid of a Government grant allotted to me by the Royal Society When a small quantity of water—half a pint—is allowed to soak gently into a given spot on a dune surface, and the dry sand is scooped away from one side of the wetted area by hand, it is found that the water has travelled farther and faster through some of the layers than through others Parallel wetted layers 1-4 mm thick are left sticking out sideways like wafers between voids a centimetre or more in thickness from which the dry sand has fallen away

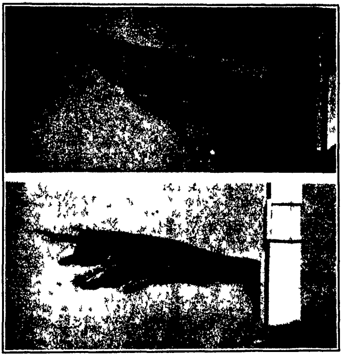

Fig 3

Fig 3 shows photographs of the structures thus exhibited, taken on the same dune surface and at spots a few feet from one another on either side of a boundary, superficially invisible, between very firm and very soft sand The upper photograph shows a firm accretion deposit through which a new top surface has been cut by the wind In the lower photograph a typical soft encroachment deposit has been laid bare by the same denudation and afterwards an accretion deposit has begun to grow on the top of it (In both cases the sand where not wetted appeared merely as a loose structureless mass, and even when wetted showed practically no structure when afterwards cleft down with a knife)

The differential rate of travel of water through sand seems to be due to variations in the effect of surface tension caused by differences in the proportion of fine grains present in succeeding layers It can be verified experimentally that water seeps faster through sand containing fine grains than through sand which does not

In the case of the accretion deposit (Fig 3), I have shown experimentally[4] that the proportion of fine grains in such a deposit is controlled mainly by the composition of the source from which the sand comes. A change of wind direction may therefore alter the fine-grain composition of the deposit, even assuming it to be growing steadily the while In the same paper it was pointed out that the process of denudation tends to concentrate on the surface both extremely coarse and extremely fine grades. There are therefore two possible causes of the variation in texture.

The cause of the laminar structure of encroachment deposits is more interesting. Since the grains reach their final resting place after avalanching down the slope, the structure appears not to be due to direct wind action. From experiments with a mixture of coarse and fine sands, each dyed a different colour, it appears that when a dry sand avalanches down a slope the finer grains become concentrated along the internal surface of shear. When afterwards wetted, the mixture shows just the same structure as the lower photograph in Fig. 3. This phenomenon does not seem to be generally known, and it may have useful applications in experimental soil mechanics.

That desert dunes are able to retain for very long periods the moisture received from rare showers of rain has long been recognized But it has often puzzled me why such patches of moisture should be found beneath the sand surface in some places but not in others nearby The explanation now seems to lie in the different structure of the two kinds of sand structure. When rain falls on an exposed encroachment deposit, the water seeps rapidly downwards along the old shear planes into depths at which it is immune from temperature changes and consequent evaporation. When, on the other hand, it falls on a firm accretion structure, it spreads out laterally along the surface layers of finer grain composition, and is hindered from sinking by the intervening layers of sand which are lacking in fine grains. It therefore remains near the surface and is soon lost by evaporation.

In all cases where I found a moist zone beneath the dry surface, and in most cases where blades of dead grass were still visible on the dunes, the sand when wetted showed the steeply dipping structure of the encroachment formation This is in accord, too, with my experience when motoring over dunes in very arid country, that areas containing occasional dead vegetation are to be avoided owing to their probable softness.

Researches in Hypnosis

IN a noteworthy article, the first to appear from the recently founded Institute of Experimental Psychology at Oxford, Dr. William Brown discusses "Hypnosis, Suggestibility and Progressive Relaxation" (*Brit J. Psych* , 28, Part 4: April 1938). Originally delivered as a lecture to the British Psychological Society, it was again communicated, in an abridged form, to the Psychology Section of the British Association in 1937. The importance of its content justified this second communication at the Nottingham meeting, when many members of other sections had the opportunity of hearing and discussing it. Dr. Brown has been well advised to have the lecture printed.

Beginning with a brief outline of its history and development from the time of Mesmer, the author even more briefly expounds his own theory of hypnotism and a technique for inducing hypnosis, which may or may not include muscular relaxation. In his therapeutic practice, however, relaxation is always induced, beginning with the small muscles of the extremities, extending to the greater muscle groups of limbs and torso, and ending with all the lesser muscles involved in speech and vision. This process not only secures a calm and tranquil state of body, but also tends to extinguish both inner speech and visual imagery, which might support conscious activity and keep the mind alert. As Jacobson has experimentally shown, progressive relaxation is of the highest importance in many pathological conditions, and of itself may effect their alleviation and even removal. Combined with hypnosis, it secures a passive and receptive state of mind, during which curative suggestions may be given to the patient with every expectation of success. The physician also pays attention to the respiration of his patient, which is normally an autonomic function, in order to induce a slow, regular and rhythmical movement of diaphragm and intracostal muscles, which makes for still greater mental passivity. Though the author does not refer to him, Heyer has pointed out that this, the only autonomic process which is also under conscious control, enables us indirectly to influence the functioning of other autonomic processes. Dr. Brown, however, lays stress upon another way of securing control over the autonomic nervous system, namely, by means of the forming of conditioned reflexes. Hudgins, using Pavlov's method, has shown experimentally that the pupillar reflex can be 'conditioned' to the sound of the word 'contract' when, just after pronouncing it, a bright light is flashed upon the eye. In time, the pupil comes to contract when the subject of the experiment pronounces the word 'contract' himself, or even thinks it, thus enlarging the scope of his volitional control, even if only indirectly. The psychotherapeutic value of this process of conditioning would seem to be evident; since, as Dr Brown points out, a word, or thought, may be associated with the operation of a drug, and in time come to act as a substitute for it

What is, however, of greatest interest in this paper is the account given of the experiments upon the patellar reflex, carried out at the Oxford Institute by Dr Brown himself, by which it was shown that normal sleep and the hypnotic condition can be distinguished by their several effects upon the knee-jerk. The subject was seated in a chair; and every ten seconds a smart tap was given on the patellar tendon by an electrically controlled hammer. The excursion of the reflex movement was recorded upon the smoked paper of a kymograph by a lever which was connected by a thread passing over a pulley to the subject's foot, thus securing a continuous record.

The method followed was to cause the subject to fixate his eyes upon a bright light, and to secure relaxation by suggestions of drowsiness, sleep and rhythmical breathing The subject becomes deeply relaxed, and, though not asleep, his knee jerks are abolished But, when suggestions of a hypnotic kind (for example, that he cannot open his eyes) are given, the reflex manifests itself again

A similar criterion of the distinction between sleep and hypnosis is found in the so called psycho galvanic (or skin constrictor) reflex The more relaxed the subject becomes, the more the body resistance rises, the less there is of 'alertness But, when hypnotic suggestions are given, the resistance falls It would seem that hypnosis is a state of peculiar, though restricted, vigilance, where as lethargy is a blend of hypnosis and drowsiness, or sleep

These and like experiments show the possibility, and indicate the importance, of extending laboratory methods to the investigation of 'abnormal and pathological states

---

The Arctic Fauna

GREAT interest in arctic exploration during the last few decades has resulted in a large number of publications on its fauna, mostly descriptive in character and restricted either to certain areas or to groups of animals The only comprehensive work on the subject is the well known Fauna Arctica,' written by numerous contributors under the editorship of Roemer and Schaudinn, which contains extensive lists of animals, mostly devoid of any general information and useful mainly for the statistics of the fauna The questions of the origin and evolution of the arctic fauna have been attacked by some zoogeographers, but their comprehensive treatment from a modern point of view was lacking This gap is now filled by Prof N J Kusnezov, who has succeeded in less than a hundred pages in presenting a remarkably concise and clear survey of the whole problem.*

The term 'arctic', as understood by the author comprises the territories occupied by the tundra proper and by the northernmost marginal belt of the forest zone with its scattered, stunted trees An up to date list of the number of species in each group of animals is given, the total being about 5 500 species The actual number of arctic species is estimated as at least three times as many The number of vertebrates, except birds, is too small to permit reliable zoogeographical conclusions, while birds, although numerous (270 species) are represented almost exclusively by non resident species, which spend in the arctic only a very short breeding period Most of the invertebrates are still insufficiently studied, but insects are represented by an unexpectedly large number of species, particularly of Diptera, Hymenoptera, Coleoptera and Lepidoptera

The existence of the arctic fauna under the peculiar environmental conditions of high latitudes undoubtedly suggests a long period of adaptation Unfortunately, the physiological aspect of this adaptation remains unstudied and is probably not the same in different groups One point, however, appears certain, namely, that the present composition of the arctic fauna is determined not so much by the thermal conditions of the arctic, as by nutritional interrelations of organisms, that is, primarily by plant life, which is mainly dependent on the peculiar seasonal distribution of daylight

As regards the taxonomic composition of the arctic fauna, it proves to be most heterogeneous, including representatives of both primitive and highly specialized groups, while there is no group that may be regarded as specially adapted to arctic conditions This complexity of arctic fauna suggests a very chequered history From a zoogeographer's point of view this history can be best made intelligible by accepting the theory of longitudinal displacements of climatic zones (Koeppen Wegener) causing corresponding migrations of animal population

Among the various historical elements of the arctic fauna an important place belongs to the euarctics, as the author calls endemic species now living only under arctic conditions, although they have no apparent ecological or physiological adaptations The primary origin of the euarctics is obscure, but in Lepidoptera, for example, a taxonomic analysis of euarctic forms points clearly to their origin from the Tertiary fauna of the Angaran continent Moreover, it is highly probable that many of the euarctics should be regarded not as postglacial immigrants into the arctic zone, but as relics of a preglacial fauna This assumption is based on quite legitimate doubts of the severity of conditions during glaciation (which is usually taken for granted) and on the existence of numerous plants and animals under most intense arctic conditions, for example, in Greenland and on arctic islands

The Quaternary glaciations resulted in a southward migration of most arctic organisms which found temporary refuges on the edges of glaciated areas This was followed by return migrations during the inter glacial periods, and these repeated movements led to the great complexity in the composition of the present Arctic population in which, apart from the Angaran elements, those derived from 'refuge areas in western Europe, in the centre and extreme east of Asia, and in the north west of North America, can be distinguished

Incidentally, the analysis of the Arctic fauna throws some light on the similar great heterogeneity of the more southern faunas, namely, the palæarctic and the nearctic, and the author insists very emphatically that the time has come when the current conception of rigidly defined zoogeographical regions should be drastically revised on the basis of modern ecological and geological knowledge and theories

The work of Prof Kusnezov deserves close study not only by those specially interested in the arctic, but also by biologists in general, since it represents a courageous attempt to discuss a wide biogeographical problem from a thoroughly modern point of view and with a healthy critical attitude towards generalizations that are generally accepted merely because they are often repeated

A good bibliography on the arctic fauna (and partly flora) comprising twelve pages concludes this interesting paper

Vegetable Poisons of Africa

DR. G. CUFODONTIS has reviewed these numerous vegetable poisons of which the native peoples of Africa have made use from time immemorial in war, hunting, fishing and the destruction of fierce and noxious animals (*Scientia*, Ser. 3, 32, 1–5; 1938). Though the use of these poisons by the natives has long been recorded by travellers, owing to lack of botanical and chemical knowledge information is often defective. Native methods of extraction are often not only complicated, but also surrounded by mystery and magical ritual, making observation a matter of difficulty.

Strophanthus, a genus widely spread over the whole of tropical Africa, is the principal source of the most powerful African poisons. Its use was recorded so long ago as 1865 by Livingstone on the Zambezi, though the actual plant used was not identified until long after. As an arrow-poison it is fatal to man and most animals, only such large pachyderms as the elephant and hippopotamus being resistant. In West Africa *S. hispidus* is used, while in Senegal and Guinea its effects have been known to Europeans by fatal experience since the fifteenth century.

The genus *Acocanthera*, of which half a dozen species are found in different parts of tropical Africa, produces a poison which, acting on the nervous system and by vaso-constriction, is even more powerful than strophanthin, an arrow wound causing death in about one hour. *A. ouabaio*, confined to Somaliland, and *A. Schimperi* in Abyssinia, Somaliland, Kenya and Tanganyika, produce a powerful poison, effective, it is said, even in pachyderms which resist strophanthin. The *adeniums*, confined with one exception to Somaliland and the adjacent regions including Socotra, are strongly toxic. They produce a latex which the Somalis use, not for their arrows, but for poisoning bait to kill destructive or dangerous animals near the villages. The active principle is a toxic glucoside which has not yet been analysed. In South Africa a strong arrow poison is extracted from *Toxicophlœa Thunbergii* and also from the bulbs of one of the Amaryllidæ *Buphana disticha*, which contains narcissin, hemanthin and a strongly toxic amorphous alkaloid, buphanin. A large family, very rich in poisons, is the Euphorbiaceæ, which contain five distinct groups of poisons. In Africa the use of poisons extracted from members of this family is confined to the Bushman, Bongos and certain Arabs, while on the east coast at Zanzibar one variety is used in fishing. Few of the leguminous plants are used, and most of these for fishing. It is remarkable that the *Strychnos* group, which in other continents produces such terrible toxic agents as curare in America and the upas poison of Indonesia, in Africa holds a very subordinate position.

Science News a Century Ago

Engineering Education at University College, London

IN the autumn of 1838, courses in civil engineering were arranged at both King's College, and University College, London. An advertisement in the *Athenæum* for September 1, 1838, said "Courses of lectures in aid of the system of instruction pursued in the offices of Civil Engineers, will be given at University College in the course of the ensuing Session.

"Every Saturday evening, from 7 to 9, Mr. De Morgan, Professor of Mathematics, will give Lectures and Praxes, the principal object of which will be to teach the application of Arithmetic to the results of Algebra and Geometry. Mr. Sylvester, Professor of Natural Philosophy, will deliver an Elementary Course principally on the Mechanics of Solid Bodies, and the Doctrine of Heat, and their application to the Steam-engine. The Lectures of Professor Sylvester will be given every Wednesday evening from 8 to 10.

"By attending a Course, or Courses of the Practical Chemistry of Professor Graham, on Monday, Wednesday and Friday from 4 to 5, the Civil Engineer will be exercised in the manipulation of testing and analysing, especially as regards mineral substances used in the arts."

Lyell and the British Association

ON September 1, 1838, Lyell wrote from his father's house at Kinnordy, Forfarshire, to his father-in-law, Leonard Horner, giving an account of his journey to Newcastle for the meeting of the British Association. He had been through Suffolk and Norfolk geologising, and at Norwich had "avoided all but collectors". The journey northward was made in one steamer from Yarmouth to Hull and then by another from Hull to North Shields. From Shields he made a long excursion to Tynemouth along the shore, went by gig to Cullercoats "where the ninety-fathom dike is laid open in the cliffs, the magnesium limestone on one side and the coal on the other", visited a railway cutting and crossed the Tyne to the Marston Rocks, "where there are lofty perpendicular cliffs of magnesium limestone, and small isolated rocks or needles of the same in the sea". At Newcastle Murchison told him he would be president of the geological section. "All that I saw of the government of the Association," he wrote, "gave me a good idea of the spirit, but no wish to consume my time in taking part in it, to which I am invited, I hear, by being put on the council. Sedgwick was so eloquent; his lecture to 3,000 people on the sea-shore made a great impression."

A Uniform System for Railways

IN 1838 Nicolas Wood (1793 ?–1865) published the third and last edition of his "Practical Treatise on Rail-roads and Interior Communication in General, etc." In a review of this edition, *The Civil Engineer and Architects' Journal* in its September number said: "It is now generally admitted that Railways must shortly become the great highways of the kingdom; and it consequently becomes an object of national importance to consider the best modes both of constructing and working them. It appears to us highly desirable that they should all be governed by one law, and all their regulations should be uniform. . . . Regretting, as we do, that the opportunity should have been lost of carrying on the railway system from the first on a uniform and consistent plan, we think that much might yet be accomplished towards this very desirable object. For this end we would recommend as a highly desirable measure, the immediate formation of what might be termed a Railway Congress consisting of one Director and the Engineer of each line. . . . Their decision should be binding on all the companies, and when necessary, they might recommend to Parliament bills for the regulation of railways, which from such a body would come supported by the high authority of extensive and practical experience."

Co-operation between the British and American Associations

IT is probable that Lord Rayleigh's term of office will mark one of the most momentous periods in the long history of the British Association To take the initiative in forming a Division to deal with the social and international relations of science is to undertake an onerous and responsible task for which the Association is peculiarly fitted and in which it will have the good wishes of all who realize the effect that advances in science may have for good or ill on the welfare of our own community and of the nations of the world at large As the Council of the Association does not meet until November the General Committee at its final meeting at Cambridge approved the appointment of a provisional committee and a few possible members of this committee were suggested to be invited to serve upon it The publication of a list of the names of these members as forming even a provisional committee is, however, premature and unauthorized

The Cambridge meeting has been signalized by yet another advance of international importance The American Association for the Advancement of Science has aims and interests which have much in common with those of the British Association and it has long been felt that a closer liaison between the two Associations would hasten the realization of those ideals of international co operation and good will and would form a very considerable contribution made by men of science to the cause of world peace

By a happy chance the principal officers of the American Association were able to be present at the Cambridge meeting of the British Association and they have agreed to transmit to their executive two suggestions, which have the full approval of the General Committee of the British Association for promoting a closer union between the two Associations It is suggested that in alternate years a distinguished American man of science should be invited to deliver an address before the members of the British Association at their annual meeting and reciprocally in the years not marked by such lectures that a distinguished British scientific worker should address the members of the American Association at their summer meeting

These addresses which will be devoted to a topic of broad scientific interest will usually but not necessarily deal with some of those aspects of science and society which are the concern of the new Division of the British Association

Further the officers of the Associations are anxious that the Associations through their members should have more intimate knowledge each of the other's work As a beginning to that end it is suggested that a number of those actively engaged in the work of either Association as members of Council or otherwise, should be elected to membership of the sister Association with the full privileges of attendance at meetings and of reception of journals

This principle of exchange of the privileges of membership may be greatly extended in the future but in this connexion much will depend on the form taken by the new quarterly journal which will replace the present annual report of the British Association after the publication of the report of the Cambridge meeting

The Associations are to be warmly congratulated on their courage and initiative in taking these steps steps which are obviously but the beginnings of others which will lead to greater understanding and closer co operation with corresponding repercussions on the friendship between two great democratic communities

Business Research

> "That which man altereth not for the better,
> Time, the great Innovator altereth for the worse "
> FRANCIS BACON

TO DAY we are almost all of us forced to think in terms of progress, although there are still some who find no interest in the idea of change and think rather of conserving the ancient values Human wants are increasing both in variety and in intensity On all sides and in all countries the standard of living is advancing rapidly The word living no longer implies food and warmth and shelter only, but includes much in the way of recreation and amusement

The present world wide state of unrest is an expression of the need for adjustment to change partly arising from the effect of scientific discovery upon the whole framework of economics politics and sociology Adaptation to new conditions always requires increased effort and has to overcome indifferent and vested interests, political and academic, just as change in industry is resisted by financial interests Whatever the attitude may be to the process, it must be admitted that we are in the presence of constant and relatively rapid change The outstanding problem in business of all kinds is that of peaks and depressions, the ups and downs of the curve of prosperity become apparently more pronounced and more frequent Planning has failed to flatten the curve, business sentiment and action are all one way at any particular moment, and the short view prevails

The consequences, both social and political, are very disturbing It has been suggested that commerce, or those engaged in it, is insufficiently educated in science to be able to grasp the potentialities of the application of scientific method to industry These changes have been brought about by engineering science almost everywhere, except in commerce as distinct from industry An example is the recent sharp rise and fall in base metals An apparent shortage encouraged a rush to buy forward and some speculation The price increase brought largely increased supplies into sight through technical activity, the buying became unnecessary and ceased, the speculators threw their holdings on a market bare of buyers, and a serious slump followed

Improvement means research, and it is indicative of the new trend that the chairman of company after company announces that organized research has become the dominant competitive weapon for their particular establishments The research is not always or necessarily scientific, but that is partly because the word science is used to indicate the applied natural sciences What is wanted by business men is a wider training in scientific method, which perhaps can best be gained through natural science The ability to weigh evidence is the faculty of the legal profession, which makes use of it to sway judge or jury In science it is Nature which has to be interpreted, and every observation should be followed to a logical end, theories should act merely as working hypotheses the greatest investigator is he who can devise an experiment to test a principle and can carry it out

In business the demands are more complex, yet the business man should at least have scientific method as the foundation of his knowledge and not regulate his activities by a series of shots which are described in city language as 'market anticipation'

Research in industry has been defined as the development of a new idea from its genesis until the time when it meets the approval of the consumer A progressive company has to be ready to introduce the new product, the new design, the new formula, with as great facility as it introduces new raw materials or new machines As the Americans say, the rate at which older markets wane establishes the rate at which newer markets must be developed This is an important principle which is not always understood, firms have been known to overdo the issue of new lines to the confusion of their customers and the detriment of their trade

The gas industry affords an interesting example of the recognition of the need of business research in catering for its customers, we make use here of Sir David Milne Watson's address to the International Engineering Congress at Glasgow Gas-fires made their appearance on the market about 1853, when an early technician remarked "to meet the wishes of that unreasoning portion of the community which liked its source of heat to be bright, two classes of stove have been designed, viz, the cheerful stoves and the class known as gas-fires". Much later, when electrical competition became a serious threat, modernization of appliances and of its whole contact with the public became an urgent task for the gas industry. Research was strengthened with the view not only to efficiency but also to appearance. In five years the new armament of the industry was forged, the enamelled gas cooker, the modern coke fire, thermostatic control, water-heaters, stream-lined coloured gas-fires, refrigerators, all became available for the public with an efficiency of twenty per cent greater than before. No wonder the industry strengthened its grip on the market and is casting around for wider fields of development

In these days of quick change, it is not surprising that the relation of industry to the State should come under consideration and that there are some who would displace industry as it is now constituted by some form of national effort. On the other hand, Prof. E H Schell, of Massachusetts, recently expressed the view that industry will continue in the main to evolve along the present lines whatever developments may take place in the social structure. The future policy of industry must be one of continuity, although it must be even more flexible to change Such change must not be emotional and hasty, but studied and calculated, the result of what has been sought to describe here as business research

Flame

Combustion, Flames and Explosions of Gases
By Dr Bernard Lewis and Dr Guenther von Elbe
(The Cambridge Series of Physical Chemistry)
Pp xiv + 415 (Cambridge At the University Press, 1938.) 21s net.

ELEVEN years ago appeared the comprehensive monograph entitled "Flame and Combustion in Gases" by Prof W. A. Bone and D. T. A Townend, followed a year or two later by "Gaseous Combustion at High Pressures" by Bone, Newitt and Townend. Except for a small volume on "Flame" by O C de C Ellis and W A Kirkby (1936), the subject has not since been treated as a whole in English, until the recent appearance of the work by Bernard Lewis and G von Elbe now under review.

The new book deals almost entirely with developments in the last eleven years, and admirably supplements Bone's books. It covers a period in which the ruling idea among many of those who have studied the chemistry of combustion is that of chain reactions, for the year after the publication of Bone and Townend's book saw the appearance in the *Zeitschrift für Physik* of Semenoff's paper on the "Theory of the Mechanism of Combustion"

The authors accept the view that chain reactions are characteristic of most processes of gaseous combustion, although "the question has to be decided in every individual case from the sum total of experimental data Sometimes there are compelling criteria, such as a large quantum yield in the photochemical reaction or the phenomenon of the upper explosion limit" (that is, the experimental fact that many gaseous mixtures can be maintained at a suitable temperature and pressure without undergoing more than very slow chemical change, but inflame at the same temperature when the pressure is reduced to a well-defined value) "In other cases it is difficult to demonstrate more than the great possibility of the chain mechanism because it is difficult to eliminate positively all other alternatives" The main criticism that has been made against the somewhat facile explanation of combustion reactions by a chain mechanism is that the postulated chain carriers have rarely been isolated from, or detected in, the reacting mixtures Moreover, it seems that each student of any one reaction postulates a different scheme for the sequence of events of his chain reaction.

The idea of a chain reaction in combustion processes has historical authority, for H B Dixon's interpretation of the catalytic effect of small amounts of water vapour on the inflammation of carbon monoxide was a chain mechanism ; carbon monoxide was oxidized by water vapour, hydrogen being set free and in turn oxidized by molecular oxygen to re-form the catalyst Much further back, Mrs. Fulhame in her remarkable "Essay on Combustion" (1794), writing of the reduction of metallic oxides by carbon, says, "water is essential to the reduction of metals in low degrees of heat—since the water is instantly decomposed by the charcoal, it is a necessary consequence, that its carbone must unite with the oxygen of the water, while the hydrogen of the latter unites, in its nascent state, with the oxygen of the metal, and reduces it, forming a new quantity of water equal to that decomposed : this new quantity of water may be decomposed in its turn : so that a thimble full of water would be sufficient to reduce any quantity of metal provided the water were prevented from escaping and time enough allowed

The authors own attempts to postulate a chain mechanism capable of explaining both the slow and the explosive combustion of hydrogen with oxygen have appeared in print hitherto in part only They now present the whole picture in some forty pages of concise exposition which covers most of the experimental results of the many workers on the subject Whether it is a true view of what happens may be questionable but the summary alone is valuable By somewhat similar schemes they describe the combustion of carbon monoxide and more hypothetically and still more elaborately the combustion of hydrocarbons

Following this lengthy but not too long treatment of the chemistry of combustion there are brief chapters on emission spectra and ionization in the flame front (6 pages) on ignition by sparks (11 pages) and on limits of self propagation of flame (5 pages) Photographic methods of recording flame movements are next described briefly with a mathematical analysis of the mechanism of combustion when an explosive mixture is ignited at the centre of a closed spherical container by the application of this analysis the speeds of flame in a stationary gas mixture over a range of pressures have been deduced from explosion records of oxygen ozone mixtures

The authors describe as burning velocity of a gas mixture what previous writers have variously called vitesse normale entzundungsgeschwindigkeit and fundamental speed of flame that is the linear speed of flame in a direction normal to its surface through a mixture at rest and at constant temperature and pressure just ahead of the flame They describe various methods of determination of this constant the analysis of which is perhaps the outstanding unsolved problem in the subject of flame propagation

Chapters on detonation (33 pages) and on thermodynamic functions of gases deduced from band spectroscopy (15 pages) leading to the calculation of explosion pressures temperatures and flame volumes (64 pages) are welcome summaries of mathematical and experimental work on difficult subjects

A short discussion of problems in technical combustion processes (29 pages) is confined almost entirely to those of internal combustion engines perhaps because the most interesting theoretical problem in technical combustion processes is that of knock in these engines

Some useful appendixes contain tabulated data on the energy contents of gases up to flame temperatures equilibrium constants of various reactions in flames heats of combustion and of other flame reactions limits of inflammability and flame temperatures

The book appeals to the reviewer as on the whole a well balanced account of modern work on flame If not unnaturally it may seem to give relatively somewhat great attention to American work most readers will nevertheless be grateful for the concise way in which the more intricate parts of the subject are expounded and co ordinated

H F COWARD

Organisms and the Earth

The Origin of Life

By A I Oparin Translation with Annotations by Prof Sergius Morgulis Pp x+270 (New York The Macmillan Company 1938) 8*s* 6*d* net

THIS book falls into three distinct parts the history of ideas on the origin of life geochemistry and the author s picture of a possible mode of development of organisms The historical part is reasonably complete and is suitably garnished with quotations from Engels but it is spoilt by occasional lapses of which it is very unlikely that Engels or his immediate followers would have been guilty A reader of the book will realize that the following sentence is no more ridiculous when taken out of its context than it was when in it No matter how minute the ultramicrobes are if they are living organisms they must be endowed with a definite and complex organisation which makes it possible for them to perform a number of vital functions

In the section on geochemistry a picture is presented of the composition of the earth s surface layer when there was nothing on it that could conceivably be described as living We have long been accustomed to the idea that the earliest forms of life were strictly anaerobic and that atmospheric oxygen is a biological product made chiefly by the green plants Oparin carries these ideas a stage further and maintains that the primitive atmosphere contained neither carbon dioxide nor nitrogen and that carbon was present on the surface of the earth either in the elementary form or as hydrocarbons The well known fact that volcanic gases contain carbon dioxide is interpreted as a present day phenomenon due to the descent of carbonate containing metamorphic rocks into the earth s interior

The third section will probably be found the least satisfactory by those readers who do not feel that any hypothesis is preferable to a suspension of judgment In it the chemical and colloid chemical processes which might be expected to take place in an environment consisting largely of hydrogen water ammonia hydrogen sulphide and an extensive range of hydrocarbons are discussed In this discussion plausible mechanisms are put forward for the origin of relatively complex molecules similar to those now found in biological material The resulting pabulum will naturally accumulate century by century until in parts its complexity becomes sufficient for colloidal phenomena to play a part and it is in a system of partially miscible liquids that the origin of life is envisaged It is possible that Oparin has taken rather too seriously Hopkins s epigrammatic description of the cell as a dynamic equilibrium in a polyphasic system

The most important idea put forward in this book is the heterotrophic character of primitive living forms It is argued that the autotrophic organisms developed from these primitive heterotrophic forms when the latter had used up so much of the available complex material that a new mode of metabolism began to have survival value The process would then continue in the manner generally assumed with the formation of free oxygen by the photosynthetic autotrophes and lead finally to the evolution of oxygen using organisms

The book is stimulating instructive and so far as the reviewer is competent to judge reasonably accurate over matters of fact The title page would have been more descriptive of the contents if it had included as a sub title Dr Oparin s answers to a scientific general knowledge paper

Symbolic Logic and the Philosophy of Science

(1) An Introduction to Symbolic Logic

By Sussanne K Langer Pp 363 (London George Allen and Unwin Ltd 1937) 12*s* 6*d* net

(2) Grundzüge der theoretischen Logik

Von Prof D Hilbert und W Ackermann (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen mit besonderer Berucksichtigung der Anwendungsgebiete Band 27) Zweite verbesserte Auflage Pp viii+134 (Berlin Julius Springer 1938) 10 80 gold marks

(3) An Introduction to the Philosophy of Science

By Prof A Cornelius Benjamin Pp xvi+469 (New York The Macmillan Co 1937) 16*s* net

(4) Die Bedeutung der Modernen Physik für die Theorie der Erkenntnis

Von Dr Grete Hermann Dr F May und Dr Th Vogel Pp viii+210 (Leipzig S Hirzel 1937) 6 50 gold marks

(1) A KNOWLEDGE of the techniques of symbolic logic is now almost essential for an appreciation of modern philosophical thought with its increasing dependence upon purely formal studies such as mathematical logic semantics and the like This introduction to the subject by the tutor in philosophy in Radcliffe College which as the author justly claims is the first of its kind is therefore particularly welcome especially as it is designed for students who are often puzzled by the seeming unrelatedness of the different branches of the subject and by the varying terminologies used

The book is planned to show the connexions between the different branches of the subject and is built around the two great achievements in symbolic logic—that masterpiece in logistics represented by the Principia Mathematica of Whitehead and Russell and the Boole Schroeder algebra It is both a text book with numerous exercises to train the student in the manipulation of symbols and an essay on these forms of logic

Thus anyone who masters the material provided in the book will be well equipped to pursue the subject further for himself in one or more of the special branches Furthermore since the author lays special emphasis upon the principles of logical construction the possibilities and limits of formalization the fundamental types of formulæ and the difference between fertile and sterile ideas the student should also be in a position to understand the epistemological problems which arise in the contemporary philosophy of science

(2) The main structure of Hilbert and Ackermann s work on theoretical logic has been retained in the second edition which appears now after an interval of ten years In the meantime the first volume of a comprehensive work in which Hilbert and his other collaborator Bernays have

applied the logical calculus in an attempt to achieve non contradiction in the foundations of mathematics has been published

The principal alterations and improvements in the present edition of the work under review, which are consequent upon advances made in the subject during the past few years, begin in the third chapter Here the rules of derivation for the functional calculus which were not formulated with sufficient precision in the earlier edition are re stated Further, since an exposition of the so called branched theory of types of Whitehead and Russell seemed no longer necessary, in view of the fact that it has become almost universally abandoned to day Chapter iv has been considerably shortened On the other hand the section dealing with the construction of the calculus of predicates of the second type and of the calculus of types itself has been both improved and rounded off The terminology of the whole treatise has been altered to conform to that of the larger work of Hilbert and Bernays Thus for example the expression 'functional calculus' has been replaced everywhere by calculus of predicates', and in accordance with current logistical terminology, the terms logical sum' and 'logical product' changed to 'conjunction and 'disjunction' respectively

(3) In this ample philosophical treatise, which is modestly termed an introduction' to a new discipline that is alternatively called philosophy of science, logic of science science of science and metaphysics of science Prof Benjamin divides his subject matter, or problems into three sections He considers the task of the philosophy of science to be, in the first place, the ascertainment of the limits of the special sciences, of their integrations with one another and of their implications in so far as these contribute to a theory of the universe or to some pervasive part of it Examination of the method of science constitutes the second part of the task and a clarification of the basic concepts and postulates of science to reveal the fundamental empirical grounds (or absence of grounds) on which they rest, the third

Thus in Part 1 of the treatise, Prof Benjamin examines such problems as logical structure, the nature of symbols perception, descriptive techniques, descriptive science and the theories of concepts represented by empiricism, operationalism, constructionalism, logical positivism and so on In Part 2 he deals with problems in the analysis of the concepts of science—number, quantity, space, time, motion, etc , and finally, in Part 3, he discusses such speculative problems as human freedom and the nature of reality He emphasizes the necessity of recognizing that the latter are dependent upon the more critical problems, and considers it fortunate that in recent years the attention of investigators has been directed principally to problems of formal logic and to those of the foundations and inter relations of the sciences He further points out, that the distinction between a general text book of the philosophy of science of this kind and an introduction to philosophy by way of the sciences, lies in the fact that the latter pays more attention to the subject matter than does this book which attempts to acquaint the student with the foundations rather than with the facts of science

(4) In awarding the Richard Avenarius Prize of 1936 jointly to the authors of these three essays on the significance of the quantum and field theories of modern physics for the theory of knowledge, the Saxon Academy of Science was influenced by fertility and originality in the ideas expressed rather than by unanimity in the conclusions Nevertheless although the treatment of the subject is different in each case, there is great similarity in the conclusions

In the first essay Dr Grete Hermann of Bremen, examines all the epistemological implications of the results achieved in modern quantum mechanics and field theories and comes to the conclusion that the only rejection required by the new theories as distinguished from classical physics and mechanics is the claim to absoluteness Further that the whole investigation of Nature from the point of view of the new theories is characterized by the renunciation of a perceptual model of any adequacy

The second thesis, by Dr May, of Gottingen, is the longest of the three, and is richer in historical and philosophical detail as well as in criticism of contemporary tendencies—logical positivism, etc —than either of the others But his researches also lead him to the conclusion that the quantum and field theories of modern physics have virtually no effect upon the theory of knowledge when the latter is considered as the science of the foundations of knowledge So far as the problem of 'rationality' as a result of the apparent renunciation by physics of the principle of causality is concerned, Dr May maintains that the relations between quantum theory and the theory of knowledge are artificially obtained by identifying causality with the ability to predict events He shows at length that logical positivism, inasmuch as it considers all *a priori* knowledge to be tautological and all that is qualitative to be merely subjective, cannot base its conclusions upon the results of mathematical physics, which admits eliminating the *a priori* deliberately, and is therefore not in a position to make any statements concerning that which it eliminates.

Radical positivism is far more concerned with practice and experiment than with knowledge and is equivalent to a calculus whereby future events in the realm of the inorganic can be predicted and whereby knowledge—as admitted by the Vienna circle—is identified with control of Nature But in Dr May s opinion knowledge is more than the logical framework of a mathematics of matter and philosophy must not degenerate into an ancilla mathematicorum

Dr Vogel of Bad Nauheim who approaches the subject from the point of view of language and philosophy considers that every advance in knowledge necessarily changes the concept of knowledge Hence the difficulty in determining epistemologically the nature of objective reality The concept reality does not belong to science at all—it lies beyond limits science from outside and changes as the frontiers of science extend But Dr Vogel thinks that in its basic structure the nature of reality will always be determined by direct experience of the surrounding world (without its ever being possible to determine exactly in what this fundamental structure consists) The thing to remember and reject is the belief—held by most practising physicists—that abstract calculi constitute the whole of science especially as the most essential feature namely the relationship between abstract quantities and experimental science can never be expressed in a calculus at all Quantum mechanics is responsible for the discovery that conditions exist which must be altered by man before he can observe them So that all we can say is that absolute knowledge does not appear to exist To which we might perhaps add the qualifying reflection that it may some day become possible to include this fact itself in an extended and more adequate theory of knowledge

AMETHE VON ZEPPELIN

Essays in Heredity

(1) The Study of Heredity

By E B Ford (The Home University Library of Modern Knowledge) Pp 256 (London Thornton Butterworth Ltd 1938) 2*s* 6*d* net

(2) The Measurement of Linkage in Heredity

By Dr K Mather (Methuen s Monographs on Biological Subjects) Pp ix+132 (London Methuen and Co Ltd 1938) 4*s* 6*d* net

THESE two competently designed books illustrate in their different ways the wide field covered by genetics They will go far to counteract the erroneous impression now prevalent that genetics is primarily composed of cytological and mathematical complexities The books obviously reflect the fact that they are written by well known practising geneticists

(1) The Study of Heredity' is designed to give an outline of modern thought on variation selection sex mimicry human genetics the species concept and other subjects concerning which many exaggerated views exist in popular imagination By describing the way in which genetical knowledge has evolved and by developing the main theme of the gene concept Mr Ford has effectively put such subjects as evolution sex and origin of variation in their proper place For those who have not had the advantage of dissecting pregnant mice (p 243) the essay well documented with facts will provide an excellent introduction to the recent knowledge of heredity It is unfortunate that the author repeats the fallacious story of the influence of temperature on red flowered *Primula sinensis* the red flowered variety does not turn white at high temperatures as is generally supposed

(2) Dr Mather s book fills a long felt want of practising geneticists who feel insecure in using statistical methods While the statistical material is fully dealt with the nature of biological experiments is always fully realized Quite frequently it is necessary to discover the significance of segregation ratios to measure linkage and to combine the results from different families Dr Mather supplies suitable statistical methods well illustrated by examples which exceptionally for a statistical book are fully worked out Novel methods resulting from the properties of the χ^2 function are provided for the measurement of heterogeneity and to meet the difficulties due to disturbed segregation ratios Finally a chapter is devoted to statistical methods for the genetical analysis of the refractory material of man The tables provided enable one to carry out all the more usual computations for genetical experimentation The non mathematical reader should be able to extract much help from this clearly written book which begins with elementary facts and carries the reader to an advanced stage in statistical methods for genetical work

F W SANSOME

Frequency Curves and Correlation

By W Palin Elderton Third edition Pp xi+271 (Cambridge At the University Press, 1938) 12s 6d net

FREQUENCY curves, correlation and sampling together form a subject in which a great deal still remains to be done, notwithstanding the progress that has been made in recent years Much of the work is necessarily highly mathematical, especially where certain small samples are concerned or where mathematical expressions for skew correlation surfaces have to be discovered These aspects lie outside the scope of the present work, but as the author says, there are few subjects which offer greater opportunity for research Prof Karl Pearson and his school have been responsible for an immense amount of the work that has resulted in practical success, and only those who have studied Prof Pearson's original work are in a position to appreciate the greatness of his contribution to statistical science In this book, the author shows that actuarial statistics can be investigated in the same way as the statistics of biology, anthropology or sociology

The advantages of any system of curves depends on the simplicity of the formulæ and on the number of classes of observations which can be dealt with satisfactorily For a complicated expression is no great improvement on the original groups of statistics and if it breaks down the statistician is left in great difficulties Furthermore if a formula be recognized as a suitable one, there must be some method of finding the arithmetical constants which will produce a good agreement in the particular case Such a method if it is to be of practical use must be simple reliable and capable of systematic application This is all the more important, inasmuch as in practice the advantages of systematic treatment are often overlooked and formulæ which have no scientific basis and no connexion with others suitable in similar cases are used in haphazard fashion by many statisticians

In this, the third edition of the book, some chapters—notably those on standard errors, the test of goodness of fit and on the correlation ratio contingency—have been re written The notation for moments has been retained Here, the author treats the 'adjusted statistical moment' as identical with the 'theoretical moment For although some writers find it convenient to use distinct symbols for the two expressions in practical curve fitting they are equated

Dictionary of Scientific Terms

as used in the various Sciences By C M Beadnell (The Thinker's Library, No 65) Pp x+235 (London Watts and Co, 1938) 1s net Library edition, 5s net

ONE result of the twentieth century inclusion of science as a general part of the school curriculum has been the greater interest shown by the reading public in popular scientific literature This interest is probably most lively in biological subjects, and Surgeon Admiral Beadnell has therefore done wisely in giving a preponderance to biological terms in his attractive little dictionary Intended for the layman, the book is as non technical as the subject permits, and many of the definitions are notable examples of conciseness and perspicuousness It would, of course, be easy to make a long list of omissions, but Admiral Beadnell has shown a sound judgment in deciding what to put in and what to leave out, and only a curmudgeon could grumble at the quality and quantity of his shillingsworth

Many readers will regret the complete absence of etymologies, but it is doubtful whether the man in the street—for whose assistance it must be remembered the book was written—will share this view The standard of accuracy is usually high, and though there are occasional slips, they are much less frequent than one might have expected in such an arduous single handed effort The author is to be congratulated upon having accomplished a very useful service to the scientific education of the layman, and his book deserves to have a wide sale A word of praise must be given to the publishers for producing the dictionary so well and at a price which brings it within the reach of even the most impecunious lover of natural philosophy The library edition is on thicker paper and is handsomely bound

The Cultivation of Mushrooms

By Dr W F Bewley and J Harnett Second edition, revised and enlarged Pp 95+18 plates (London Anglo Scottish Press Ltd, 1938) 3s 6d net

THIS second edition is a considerable extension of the first edition published four years ago The authors are well known authorities on the cultivation of mushrooms, and they have made not only commercial cultivators of this plant but also botanists in general indebted to them for a coherent and very practical account of all the processes involved from beginning to end

It is difficult to imagine any query arising in connexion with the cultivation of the mushroom which remains unanswered in these pages Apart from details of cultivation, diseases and pests and even cooking recipes are considered The book is written in a pleasing style, and is illustrated by a few line diagrams and about forty excellent photographs

Organic Chemistry:

a Textbook for Science and Medical Students By Dr Frederick Prescott and Dudley Ridge Pp viii+688 (London University Tutorial Press, Ltd, 1938) 8s 6d

THIS book claims to cover the organic chemistry required by second year medical students and by students reading for a general B Sc degree, the claim is not exaggerated The wants of the former are met by sections on carbohydrates, ureides and purines, proteins and fermentation and enzyme action which occupy nearly a hundred pages, and other sections having physiological bearings deal with hydro aromatic compounds (terpenes, sterols, etc), indole derivatives and the alkaloids

The remarks on modern theories of valency (pp 29–35) may need modification in a future edition, since views change so rapidly

The R.R.S *Research*

FURTHER information is now available about the progress in the construction of the R R S *Research* It may be recalled that the purpose of this vessel is primarily the determination of the magnetic elements at sea work that was formerly undertaken by the S S *Carnegie* a non magnetic ship operated by the Carnegie Institution of Washington The *Carnegie* was unfortunately destroyed by fire after an explosion when loading petrol at Samoa nine years ago During the intervening period the magnetic data in certain parts of the oceans have become uncertain it is known that in some areas there have been considerable changes in the secular variations of the magnetic elements which are not adequately controlled by recent observations In certain areas existing charts of the magnetic declination may be in error by four or five degrees It is fitting that Great Britain as the principal maritime nation should accept the responsibility for the work formerly undertaken by the Carnegie Institution by constructing and operating a non magnetic ship

As in the case of the *Carnegie* the work of the *Research* will not be restricted to terrestrial magnetism Certain work in meteorology atmospheric electricity and oceanography will also be included

The construction of the *Research* which was authorized more than three years ago has taken longer than that of a normal ship The greatest care is being taken to eliminate so far as is possible and practicable all ferrous material from the hull machinery and stores The construction of a vessel of so specialized a nature necessarily gives rise to many problems The Department of Terrestrial Magnetism of the Carnegie Institution of Washington has placed all the information obtained from the *Carnegie* freely at the disposal of the British Admiralty This generous co operation should greatly help to ensure the success of the *Research*

The new non magnetic ship will be larger than the *Carnegie* Her loaded displacement will be 770 tons the length on the water line being 142 ft 6 in The hull is being constructed of teak planks on brass frames subdivided by eight water tight bulkheads and will be copper sheathed The keel stem and stern posts are of teak and the false keel is of Canadian rock elm The ship will have two masts and will be rigged as a brigantine with a full sail area of about 12 000 sq ft Diesel oil engines of 160 B H P four cylinder two-stroke direct air reversing type situated aft driving a two bladed feathering propeller will give an endurance of 3 000 miles with a fuel supply of 14 tons of heavy oil Much research work was carried out by the makers Messrs Petters of Yeovil to reduce the quantity of steel in the engines to a minimum A bronze alloy is being used extensively and the crank shaft is of special non magnetic steel The anchors cables and wire for rigging are of aluminium bronze

The auxiliary machinery comprises two 9 H P and one 18 H P Diesel engines for the dynamos refrigerator air compressor and oceanographical winch The latter will be driven from the auxiliary engines through line shafting and a fluid flywheel

In order to reduce magnetic material to a minimum consideration is being given to such matters as iron nails in packing cases tin containers for food and cigarettes cooking utensils cutlery razor blades drums for paint and lubricating oil and typewriter all of which will be non magnetic Water (37½ tons) will be carried in specially designed teak tanks and there will be 120 cubic feet of cold storage

The upper deck will carry two magnetic observatories an atmospheric electricity laboratory and an oceanographical laboratory The marine deflector for the determination of the horizontal intensity of the earth s magnetic field will be housed in the forward magnetic observatory this instrument is a semi absolute instrument the instrumental constant being controlled by land observations as frequently as possible The marine collimating compass for the determination of the magnetic declination will be placed on the bridge deck above the chart room The after magnetic observatory will contain the marine earth inductor which will be driven at a constant speed by a rotary converter controlled by tuning fork the inductor will be provided with commutator and slip rings so that observations may be made using either a direct current or a string galvanometer A C I W magnetometer earth inductor and a Smith portable magnetometer will be carried for land observations and for comparison with the instruments at fixed observatories

The atmospheric electricity laboratory will be situated immediately forward of the aft magnetic observatory A potential gradient recorder and a point discharge apparatus will be carried The potential gradient observations will be standardized by a Wulf electrometer In addition, ionization measurements will be made with a modified Ebert apparatus and conductivity measurements will be made with a modified Wilson apparatus

The meteorological equipment will include thermometer screen with thermometers mercury barometer aneroid and barograph mercury in steel thermographs for dry and wet bulb temperatures and for sea temperatures an Assmann psychrometer and an Aitken nucleus counter

An oceanographical laboratory will be provided aft of the aft magnetic observatory Echo sounding apparatus will be carried

It is expected that the *Research* will be launched in February 1939 and will be ready for her first cruise in the following October She will carry six officers four scientific workers and twenty two petty officers and men On her first cruise she will first visit Washington in recognition of the assistance given by the Carnegie Institution after calling at the South American ports she will cross the Atlantic and make observations in an area in the South Atlantic between and south of Tristan da Cunha and Cape Town In this area there has been a large decrease in recent years in the secular change of the magnetic declination The *Research* will then make a double traverse of the Indian Ocean first on approximately a great circle track to Perth and then returning on a more northerly track calling at Cocos Island Colombo Seychelles Mauritius and Durban where she is due to arrive about November 1940 The subsequent course has not been decided upon in detail but may include a third crossing of the Indian Ocean and a return via the Pacific and the Panama Canal The Indian Ocean will be the area to be the most completely observed on the first cruise since it is in this area that there is the greatest uncertainty in the magnetic data

H S J

Eye and Brain as Factors in Visual Perception*

By Dr R H Thouless

THAT we see with our eyes is known to everyone and has been known for a long time That we see also with our brains is less generally realized and the implications of this fact are relatively recent importations into the theory of vision The full statement of the physiological mechanism of vision would include not only the sensitive retinal surface and the visual areas of the cortex but also the whole system which includes retina optic nerve visual area of the cerebral cortex and other sensory areas of the brain as well

TRANSMISSION THEORY OF VISION

It is possible of course to study vision in such a way that everything except the activity of the retina is neglected altogether or relegated to a secondary position and it was in this way that the scientific study of vision began This is the point of view which we find in the work of Helmholtz and in much of the experimental research into vision which has followed his deservedly great authority The basic assumption is that the essential process of vision is the formation of an optical image on the retina and its transmission to the visual centres of the brain by means of the optic nerve Differences between the sensations transmitted to the brain and the finished perception which appears in experience were attributed to the action of the higher processes of judgment and the influence of past experience

This theory of vision which we may call the transmission theory has behind it not only the weight of the authority of the great originators of the experimental study of vision it has also the advantage of being the view of the man in the street Its truth seems to many to be so axiomatic that its denial may have the appearance of wilful paradox

It is nevertheless now clear that the transmission theory is wrong and that a wholly different way of approaching the problems of visual perception is necessary if we are not to be led astray To say this is not to deny the greatness of the achievements of those investigators in the past whose work on vision was guided by this theory Within a certain limited field it proved itself a fruitful guide to research This field was that of the sensory physiology of the retina If we wish to discover what is happening on the retina we must arrange conditions of experiment so as to cut out so far as possible the complicating effects of the cerebral components of the visual part of the nervous system This was what was done when the early experimenters made observations through tubes or on black backgrounds So such workers as Helmholtz König Abney and a host of others made a firm foundation for a science of vision in the sensory physiology of the retina The error however has sometimes been made of mistaking the foundations for the completed building When we get rid of tubes and black backgrounds and open both eyes to look at objects surrounded by other objects we find that what we see follows other and far more complicated principles than the laws of sensory physiology

---

* From the presidential address to Section J (Psychology) of the British Association delivered at Cambridge on Aug 19

AN ALTERNATIVE WAY OF TREATING VISUAL PERCEPTION

We place on a table an elliptical object with its long axis pointing directly to and from the observer If his head is directly above the object it will of course look elliptical If now he moves his head from the position directly above but still keeping it in the vertical plane passing through the long axis the object will at first still look elliptical but with a smaller apparent elongation than when it is viewed from directly above If the head is now lowered but still kept in the same plane the apparent shape of the object becomes nearer and nearer to a circle It then becomes truly circular and if the head is still further lowered the object appears elliptical again only now with the really longer axis apparently the shorter

So far everything appears to be as one would predict on the transmission theory by the elementary principles of perspective Measurement of the actual angles at which these various appearances are found reveals however a considerable discrepancy from the expectations aroused by the transmission theory At the height for example at which the ellipse looks circular it is found that the retinal image is not of a circle but of an ellipse with the vertical axis much shorter than the horizontal that is an ellipse flattened in the opposite direction It is as if the shape that is seen (the phenomenal shape) is in between the real physical shape of the ellipse and the shape that is projected on the retina (which we may call the stimulus shape) The expectation on the transmission theory would be that the stimulus shape and the phenomenal shape would be identical Plainly they are not and the discrepancy is large enough to show clearly without any great refinement of measurement

We are led from consideration of this experiment to the same conclusion as was arrived at by Werthiemer as a result of his experiment on phi movement that the sensation corresponding to the conditions of local retinal stimulation as an element in a complex perception is a mere fiction Although it is clear that the conditions of local retinal stimulation affect the resultant perception we can find no trace of evidence that they do so by being transmitted to the brain as sensations

The transmission theory is easily intelligible because it can without difficulty be explained by a physical analogy Photographs might be transmitted telegraphically by forming an image on a plate made up of a large number of small photoelectric cells each of which is connected by a wire with a corresponding reproducing cell at the other end This is not of course the method actually used for the telegraphic transmission of photographs but it is physically a possible one If the receiving electric cells are replaced by the retinal organs the transmitting wires by the fibres of the optic nerve and the reproducing cells by the nerve cells of the visual centres of the cerebral cortex we have a perfect analogy to the physiological process of vision on the transmission theory

Yet this advantage of simplicity and easy intelligibility must be given up if the transmission theory does not fit the facts We have so far criticized it only in connexion with one experiment Perhaps this will be a convenient place to summarize the whole case against it

First there is a physiological difficulty as to the mechanism of transmission Such a method of transmission as is suggested by the above analogy would require a number of wires equal to that of the receiving cells This condition is not fulfilled by the visual system since the number of retinal end organs is two hundred times as great as the number of fibres in the optic nerve

Secondly a breach in the transmitting part of such a system would lead to a corresponding gap in the received picture This expectation is not fulfilled in vision We might explain away on the transmission theory the fact that we do not see a gap in the part of the monocular visual field corresponding to the blind spot but Fuchs has shown that similar completion may take place over a blind area of the retina caused by an acquired destruction of part of the optic nerve

Thirdly if this theory were true it would be necessary that differences in the picture at the sending and at the transmitting end should always accompany one another The experiment already discussed has given one example of that not being the case since the impression of a circular shape may be given either by the circular retinal image given by a circular object at right angles to the line of vision or by a retinal image which is a flattened ellipse if this is made by an object which is itself an elongated ellipse viewed at a suitable angle of inclination

There are plenty of other examples of this in visual perception indeed except in those conditions of simplified perception which were characteristic of the early investigation of visual sensations exact correspondence between the details of the retinal image and of what is perceived is the exception rather than the rule In Rubin s reversible figures for example we may have a pattern which is seen either as a row of black T s on a white ground or as a row of white fleurs de lys on a black background Thus we have a single stimulus pattern on the retina giving rise to two wholly different perceptions The after image of a circle moreover, will look large or small as it is projected on to a far or a near object respectively although the area of retinal activity remains unchanged If a subject seated below the object glass of a projection lantern looks at a picture projected on to an inclined screen, he sees the picture as distorted, although it is easy to demonstrate that his retinal image is identical with that which he would have received if the screen had been at right angles to his line of vision

Such facts as these are not easily reconcilable with the theory of simple transmission of a retinal picture to the brain That there is a close relationship between the condition of physiological stimulation of the retina and of the resulting pattern of visual perception is, of course, obvious and is denied by nobody but the relationship may not be of the kind suggested by the analogy with telegraphic transmission

A better analogy for the modern view of perception is I suggest the construction of one of the charts published with weather forecasts The lines of equal pressure on the charts are constructed from information received from various land stations and ships, just as the perceptual picture constructed by central activity depends on information received from the sense organs If no information as to barometric pressure is received from a certain area, this does not mean that the corresponding area must be left blank, but that the person constructing the chart must fill it up by guess work which he generally does by constructing smooth curves consistent with the other information In the same way, in Fuchs's experiments, it was found that central perceptual activity tended to fill in areas from which no information was received from the retina by simple completions providing good continuation' with the figure received on the rest of the retina

The analogy of the construction of a weather chart suggests a possible way of looking at the process of visual perception which is alternative to the transmission theory and which, I think, gives a much better account of the experimental facts It regards the mind (or the brain acting to some extent as a unitary whole) as active in perception, responding to information given by the sense organs and not merely reproducing a pattern of stimulation from the sense organs

INDIVIDUAL DIFFERENCES IN VISUAL PERCEPTION

Let us now return to the experiment with the inclined ellipse to note a particular feature in it which is, I think, a characteristic of the perceptual processes that has often been ignored This feature is the wide range of individual differences Apart from such obvious differences as errors of refraction, colour blindness, etc , the optical system of different individuals' eyes and consequently the conditions of local physiological stimulation on the retina for a given arrangement of external objects is very much the same The perceptual responses of different individuals are however, widely different, so that any two of us in the same physical surroundings may create from them a very different phenomenal world

If two or three people perform the experiment I have just described, we shall find that the height at which they say the apparent shape of the inclined ellipse is circular is different to an almost incredible extent One may see the ellipse as circular when his head is only a few inches from the table so that his retinal image is of a very much flattened ellipse, while another sees the ellipse as circular when he is looking well down on it, so that his retinal image is itself not very far from circularity The first individual shows a very great effect of the real shape of the ellipse in determining its apparent shape, the second shows a relatively smaller effect of the real shape on apparent shape

That these are real individual differences and not merely accidental variations in measurement is shown by the fact that they show great consistency from one time to another I once retested, after an interval of two years, a group of twenty five subjects for each of whom I had measured the apparent shape of an inclined object They differed widely amongst themselves at each test, but the agreement between the two sets of tests was extraordinarily high The coefficient of correlation was 0 92, which is as high as one expects to get in psychological measurements

There are, then, genuine and large individual differences between different persons in the apparent shapes of inclined objects We may add that there are similar individual differences in the apparent sizes of objects at different distances and of the apparent whiteness of objects under different illuminations In both of these cases, the same general law holds If an object is moved to twice its previous distance from our eyes, it does not look half its previous size It may, for different individuals, look threequarters of its previous size or nineteen twentieths With rare exceptions (which I shall mention later) the law holds that the apparent size is in between the retinal size and the real size In the same way, if a piece of white paper is put into shadow so that it reflects less light to the eyes than a brightly lighted piece of black paper, it does not necessarily look less white than the black paper, although it may do so if the shadow is very deep The seen whiteness is in between the real whiteness and the stimulus intensity of the retinal image Again in this tendency to see objects in their real whiteness irrespective of illumination we find wide individual differences I have suggested that we should call these effects the tendency to phenomenal regression to the real characters of objects

If we test a group of subjects in their tendency to phenomenal regression for shape for size and for whiteness we find that those who have a large tendency to see the real size of an object tend also to have a large tendency to see the real shape and the real whiteness The correlations between these tendencies are about 0 6 which shows that they have a considerable factor in common We can thus speak of individuals as having high phenomenal regression if their perceptions of apparent shape size and whiteness are largely determined by the real characters of the objects looked at while those whose perceptions are determined relatively more by the conditions of retinal stimulation (that is who see objects getting much smaller as they go farther away and so on) we shall describe as those of low phenomenal regression

Practical Consequences

It may be asked whether the kind of thing we have been talking about has any practical importance It certainly may have We test for such differences in the sensory physiology of the eye as colour blindness because they may lead to practically important incapacities and it is very likely that individual differences in the cerebral side of perception may also affect an individual s practical capacities Some years ago I suggested that a person of high phenomenal regression might be expected to drive a car more easily through traffic than one with low He sees a gap in the traffic in something near its real size before he drives up to it whereas the person with low phenomenal regression sees it as smaller than it really is when it is at a distance Neither of course adjusts his driving to the apparent size of the gap both must make a judgment as to its real size The person with low phenomenal regression has however a much larger gulf between appearance and reality to bridge by means of judgment Judgment being a slower and more uncertain process than perception he may be expected to drive through gaps with more difficulty and less certainty than the individual who can trust to his immediate impression of size The individual with high phenomenal regression may therefore be expected to drive more easily and better through traffic This prediction appears to have been justified by a research in motor car driving by the National Institute of Industrial Psychology when it was found that a test of phenomenal regression showed a correlation with driving ability

The effect of drugs on individual organization of phenomenal space is an interesting problem I have made only preliminary experiments on one subject in the hope that someone better equipped to experiment on drugs will take the inquiry further The indication I obtained was that (as might be expected) alcohol decreased phenomenal regression while caffeine increased it I think that it might be worth while for those investigating the effect of alcohol on motor car driving to consider the possibility of disturbance of spatial perception as well as of speed of motor responses That a change of spatial organization can affect driving I am sure from personal experience I was driving one night towards Buxton suffering from the effects not of alcohol but of fatigue (which probably affects spatial organization in the same way as alcohol) At one point I found my perception of the road so much disturbed that I had to stop my car and get out The road seemed to narrow almost to a point in front of me I seemed to be driving not on a parallel sided track but into a funnel I recognize the condition now as one of extreme reduction of phenomenal regression One result of this condition was an almost irresistible impulse to drive in the centre of the road A persistent tendency to drive on the crown of the road is a common fault I suggest it may be a fault characteristic of an individual with low phenomenal regression and that if this were proved to be its origin an understanding by the driver of the cause of his fault would put him into the way of correcting it

Conclusion

The change that has taken place in the psychological study of vision during the last twenty five years may be expressed in a summary way as a change from the time when it was treated as if vision were a function of the eye alone to a time when the eye and higher centres are regarded as co operating in visual perception The psychology of vision is not and cannot be merely the sensory physiology of the eye At the present time these wider aspects of visual perception offer a more fruitful field of research than do those of sensory physiology which have been so adequately dealt with in the past Particularly I should like to suggest that individual differences in visual perception and the statistical study of these differences is a field the surface of which has scarcely yet been scratched Let us hope that in the next twenty five years psychologists may be as successful in resolving the many remaining problems of visual perception as were the great Helmholtz and his contemporaries in making a scientific study of the sensory physiology of the eye

Contacts of Science with Social Problems

By Prof G A. Boutry, Directeur du Laboratoire d'Essai, Paris

PROSPEROUS States and societies are in a state of statistical equilibrium somewhat comparable for the purposes of argument to the state attained at the end of a limited chemical reaction If we consider our present civilization such a stable state seems to exist no longer and the departure from moving equilibrium must indeed be large since everybody agrees about its existence That one of the causes of this new—and uncomfortable—state of things is to be found in the ever accelerated industrial and scientific development or rather in the social sentimental and ethical aspects of our world lagging behind that development few people would now care to deny

This means that science—the word is here used to signify the natural sciences—has slowly come to have a social and *political* importance of the first magnitude There is no reason to insist upon this idea which has been often stated and discussed in NATURE A century ago politics and science had only a nodding acquaintance the influence of the second on the first has since grown more and more powerful more and more *direct* until at last a development which could have been foreseen so early as the beginning of this century has taken place Men in various countries speaking severally have claimed in the name of science a share in the ruling of nations This claim—which has had its echo in the columns of the present journal—is far reaching and important enough to attract study

Common sense points out that Science being only a spiritual construction made up of countless sheets of thought laid up and sealed by countless dead or living men has no separate and discrete existence no personality no will and no power to act Scientists being men possess those properties men who are not scientists also do Therefore when we hear someone speaking in the name of science about political matters three possibilities are to be considered namely (1) the speaker is a politician influenced by scientific ideas (2) the speaker is a scientist influenced by political or non scientific ideas (3) the speaker is a scientist interested in a new field of application

In the first instance by the term politician influenced by scientific ideas we allude to those men whose speech has caught the knack of scientific wording but whose minds continue to run along the well worn political grooves The political language has a marvellous way of generalizing and distorting ideas principles and laws We have seen during recent years outstanding examples of such a technique and the world is teeming with such attempts Racism is nothing else than a provocative distortion and generalization of well known biological results yet it seems to have become powerful enough to rule a great nation Another and much older example of the curious sentimental reactions and upheavals which a badly understood scientific theory may originate is to be found in the anti Darwinist movement in the United States which so I am told is still discussed there from a religious point of view It is unnecessary to give more historical examples of this kind they are well enough known These contacts between misunderstood science and politics are not the principal object of the present paper Indeed they would be dismissed with contempt if their advent was not in itself a danger to science a risk of creating in the mind of men uncalculated aversion for the innocent techniques thus misunderstood or misapplied

Far more interesting is the same claim when it is made by real scientific workers It is not intended here to contest the principle that if a little more scientific thinking were used in the ruling of countries some blunders would be avoided and some progress made What has to be considered is the claim as to a proposed scientific experiment and treating it as such to find whether that experiment has any limitations (voluntary or otherwise) whether it can be stopped and started again at will whether finally it will endanger in any way the human commonwealth already acquired It is at once evident that caution is necessary the experiments of a mathematician are dangerous only to his paper supply those of a physicist or chemist may raise the roof of his laboratory and reduce him to small particles those of the biologist or pathologist may be fatal to thousands of people What can be said of an experiment in the science of ruling nations ? Wars have shown that mistakes in this art have led to the death of millions and the misery of generations it is conceivable also, that they may be dangerous to the spiritual qualities of mankind since we know next to nothing about this side of things

It follows that great pains must be taken to ascertain that the claim we are considering is pure We have seen Governments making a masquerade of scientific principles Scientific workers being human might do the same and could be infinitely more dangerous since the disguise would be much better worn If a man of science is moved on such a course by purely personal motives or feelings such as money lust of power family politics etc the process is generally petty and cheap as it is in ordinary political life and the activities of the man will cease when he reaches his small goal Very different is the result of a metaphysical bias The mixture of metaphysics of any kind with scientific theories and results is constantly occurring in second rate scientific minds and it is very easy to understand such a mixture leads to single minded pictures of the world generally easy to grasp these appear endowed with absolute fixed immovable properties rules and laws this again is very satisfying to the human mind as creating what one of this school aptly termed a rational religion One is led along such a line of thought to the idea that science rules the world and that no principle of hers may be transgressed by Nature From such a conclusion it is evident that rules of government may be deduced and that further experiments to prove them are unnecessary this is why such schools of thought (which are as old as science itself) are always unable to admit failure if facts disappoint their hopes facts are wrong and if people do people should know better or had better die

The first modern trials at scientific interference of this kind have already happened One born in the United States based upon a misunderstood conception of the principles of thermodynamics was called technocracy Another is slowly developing in the U S S R where the simple creed of Marxism is slowly being replaced by the metaphysic faith known as empirical materialism Another born in France recently of the same principles as the Russian theory can be followed and studied in its rapid growth in the sayings and doings of some well known physicists of that country The 1937 Congress of the Palais de la Découverte afforded in its opening speeches some good examples

From these views it would be gathered that science supreme master is not the servant of men but should be served by them thus new gods are born in fair disguise they are no longer anthropomorphic but they are still man made It is indeed a shattering thought for those who hope in the ultimate progress of humanity to remember that misunderstood Christianity in old days was a foe of science, while a new religion can be now found in the principles of thermodynamics and statistical mechanics It is another shattering thought to reflect that most of the men who fall into such errors are sincere and therefore powerful leaders of men Have we made no moral progress since the spectacular failure of Auguste Comte and of his religion de l humanité ?

Let us now consider the last kind of claim that laid by fair minded men who consider that a new field of application will be shortly opened for scientific thought through the helpless state of most political Governments in this our world Indeed we all feel it is highly desirable and urgent to make a start But we are also convinced that prudence and humility must be the order of the day—rashness and pride would be fatal to this new born cause We must always remember that this application of scientific training reasoning and principles to a field where the work already done is scarce and of a fragmentary character will be the biggest extrapolation that science has ever attempted

It must always be remembered that experiments may fail and while being ready to accept such failures and take them into account we must keep before our mind the fact that social experiments are costly and that failures must be few and far between in ancient days experiments on living men were impossible—they are still rare and difficult so will be experiments on nations Also we must never forget that this new development of science must introduce new variables into its reckoning that it must be human while remaining impersonal that it must build a world not only efficient but also happy From this point of view problems such as that of human liberty (its scope and limitations) sexual relations the fostering and development of intelligence appear as peculiarly dangerous since few more mistakes can be allowed in their treatment Indeed had science only to deal with the financial conduct and foreign relations of nations its task would appear almost light compared with the heavy burden it is now preparing to shoulder It is however certainly high time for the proposed organization of the study of social relations of science to be established and NATURE is to be congratulated since this journal was the first to urge its necessity

[To prevent possible misunderstanding it should be stated that the above article by Prof Boutry was written by him several weeks ago and submitted for publication in NATURE long before the recent Cambridge meeting of the British Association at which it was decided to constitute a new Division of the Association to be concerned with social relationships of science —Editor of NATURE]

News and Views

A Founder of the Institution of Electrical Engineers

ON September 5 occurs the centenary of the birth of Major-General Charles Edmund Webber, who in 1871, with Colonel Sir Francis John Bolton (1831–87), was instrumental in founding the Society of Telegraph Engineers and Electricians, since 1889 the Institution of Electrical Engineers Webber, who was the son of an Irish clergyman, passed through Woolwich Academy and in 1855 received a commission in the Royal Engineers After service in India, he became an instructor in military surveying at Woolwich, and in 1866 was attached to the Prussian Army to report on engineering operations and military telegraphs His knowledge of the latter led to his being lent to the British Post Office in connexion with the organization of the telegraph service, and it was while engaged on this service in 1871 that with Bolton he founded the Society of Telegraph Engineers, of which Sir William Siemens became the first president Bolton was for some time the honorary secretary, while Webber was elected to the presidential chair in 1882 He had just previously, in 1879–80, been through the Zulu War, and in 1881 had served as British Commissioner at the Electrical Exhibition In 1882 and 1884 he again saw active service, this time in Egypt, and in 1885 retired from the army with the rank of major-general. He was afterwards connected with several electricity supply undertakings and was elected a member of the Institution of Civil Engineers, being, it is said, the first military officer to qualify for election He died at Margate on September 23, 1904

Protection from Air Raids

THE scheme of air raid protection prepared by a committee of scientific workers, including Profs J B S. Haldane, J. R. Marrack and J. B Bernal, working in conjunction with engineers and medical men, and recently submitted to the Home Office, presents what may be regarded as a scientific and technical view of the best preparation against the eventuality of air raids The scheme, which is also being placed before the L C.C and all the London Borough Councils, has been prepared at the instance of the Science Commission of the International Peace Campaign and might with advantage be studied by all who take an interest in this matter. Because it combines an important strategic centre containing three main line railway termini, a better-class residential district with many open spaces, and a densely packed working-class area, the Borough of St Pancras was chosen as typical of the conditions to be dealt with and has been made the basis of a typical scheme worked out in broad details. Experience in Spain and China shows that air raids now are of a very different character from those of the Great War and that the civilian population has become a definite objective. The scheme is based on the assumption that all four types of attack—machine guns, gas, incendiary bombs, and high explosive bombs—may be used either separately or in conjunction, and figures are quoted as to the destructive and penetrative powers of these weapons.

THE Commission proposes the evacuation to the country of children up to fourteen years of age, the mothers of infants, people over seventy years of age and the sick and infirm For the rest of the population shelters are proposed, and these take the form of tunnels in the London clay 50 ft below the surface, of inverted U section and lined with steel sheeting. In the design of these, provision has been made for every necessity which it is possible to foresee Some of the suggestions made deserve consideration on the broader ground of their intrinsic value in times of peace, for example, that hospitals should now be built in the country, and that school camps be prepared for children of school age Such a scheme as is here proposed is necessarily of a tentative nature, but the work of the Committee has reached the stage at which its publication is of value to the public and the details of the scheme are sufficiently clear-cut to stimulate criticism, suggestion and discussion which will lead to modifications and improvements Copies of the memorandum can be obtained (price 3*d*) from F J Sander, 85 Beechwood Road, Sanderstead, Surrey

Radcliffe Observatory, Pretoria

NEWS has recently been received from the Corning Glass Co that it has been successful in the third attempt to make a Pyrex disk for the 74-in reflector of the new Radcliffe Observatory, Pretoria. The glass is now being shipped to Newcastle, where grinding and polishing will be commenced immediately by Sir Howard Grubb, Parsons and Co. Meanwhile, work on the site at Pretoria is proceeding satisfactorily, and erection of the turret and the telescope mounting should be completed by the end of this month The turret steelwork is all assembled, including the shutters, and the outer sheeting has been fixed in position. The telescope itself is practically entirely erected, despite some difficulty which was encountered in procuring lifting tackle sufficient for handling the heavier parts, especially for the polar axis, which when fitted with its circles, etc., weighs 16 tons. The tasks now remaining are concerned chiefly with the electrical equipment. Subsidiary apparatus, all of new design, is still under construction in Great Britain. A measuring machine for spectrograms has been finished and has passed thorough tests, a microphotometer is near completion, and work is in active progress on a Cassegrain spectrograph. Dr. T. Dunham, jun., of the Mount Wilson Observatory, is preparing plans in conjunction with the Radcliffe staff for a large spectrograph of very advanced design, which it is hoped will be installed at the coudé focus very soon after the new reflector comes into operation

Biblical Botany at the Hebrew University

STUDY of the flowers of the Bible has just been introduced to the Hebrew University at Jerusalem as a subject for students, who are showing considerable enthusiasm for it. Coupled with biblical botany is the study of Jewish and Arab plant-lore Dr. Ephraim Hareubani is the lecturer, and he brings to his task thirty years of research into the flowers and plants mentioned in holy scripts Together with his wife, also a botanist, he has collected almost all the specimens named and, using Mrs. Hareubani's own methods of preservation, has placed the whole collection in the University's Museum of Biblical Botany. He has identified and classified all the plants of ancient Palestine, Syria and Babylon mentioned in the Bible, the Hebrew Talmud and later Jewish writings. A conspicuous feature of the Museum of Biblical Botany is the fresh-looking appearance of the permanent exhibits which, without pressing or bathing in liquids, seem as though they have just been plucked, and retain their original colour and greenness of stalk. They are displayed in their natural groups in sealed cupboards Among the many curious plants may be mentioned a species of *Capparis*. This blooms, matures and dies in a single day, and, by the exercise of considerable patience and vigilance, Dr. Hareubani has been able to show it in a series of half-hourly stages of growth

STUDY of botany on a scientific plane was first begun in Palestine by Dr. Alexander Eig, late director of the Department of Botany at the Hebrew University. His researches, from 1921 onwards, led him to Syria, Turkey, Kurdistan and the desert tracts, and he built up a comprehensive collection of Near Eastern flora The Palestine plants he classified according to the geographical and climatological types of the world groups (the country comprises two different floral regions), and he published a remarkably detailed phytogeographic map of Palestine. According to Faba Turovlin, broadcasting from the Jerusalem wireless station, "by following Dr. Eig's observations on the subject, the character of any particular district in Palestine may often be learned from the study of its plants, and in some cases from the occurrence of a single plant only". There is now periodically published a *Palestine Journal of Botany*.

Excavation of a Hill Fort in Sussex

THE hill fort or camp at Mount Caburn, near Lewes, which is under excavation by the Brighton and Hove Archæological Society, continues to yield interesting results. The investigations have now revealed the character and constructional history of the ramparts in some detail. According to a report on recent work (*The Times*, August 25), excavations in the upper rampart show that, when first constructed, it was retained by a line of posts and a net palisade. A channel in the chalk indicates the line of the palisade The second stage of the outer rampart, which covered the final period of occupation of the camp, is indicated by the fact that the original rampart was reinforced by a mixture of chalk and black mould Post holes show that the rampart was further strengthened by fresh timbering. On the south side of the gateway a long cut has shown that the inner ditch had been filled up by the slipping of the inner rampart Occupation floors of huts are clearly evident There is no trace of occupation during the neolithic period, but a small piece of bronze has been found.

Archæology and the Unemployed at Oxford

OXFORD, like the Irish States (see NATURE of June 11, p 1041), has made use of measures for the relief of unemployment to further archæological studies. Voluntary labour from the Oxford and Wales camps of the Universities Council for Unemployed Camps has carried out excavations on Farington Clump during two seasons, proving it to be the site of the Adulterine Castles raised by Robert of Gloucester against King Stephen In 1937, excavations were begun on a Romano-British and early Saxon cemetery site at Frilford Here, under the direction of Dr L. H Dudley Buxton, members of a camp near Eynsham, consisting of ninety men from South Wales and twenty-five university men, worked daily on the Romano-British area. They located six graves and established the north-western limits of the cemetery A hoard of thirty coins made it possible to date the site with some precision The Saxon area is of special interest, as it is one of the sites, rare in Britain, which was in continuous occupation during the period of Saxon penetration Excavations are being continued at Frilford and on a site in the north of England The men, some of whom have been out of work for years, showed a ready response, both technically and intellectually, to archæological training, and their interest in the results was keen The three weeks in camp produced a marked improvement in physique Funds for the continuation of this work are urgently needed, especially as the applications from clubs for the unemployed are increasing. Contributions may be sent to the treasurer of the appeal, Mr. J Kelly, 16 Charlbury Road, Oxford

Insulin Treatment of Diabetes

PROF. CHARLES BEST, of Toronto, delivered the twelfth Stephen Paget Memorial Lecture at the annual general meeting of the Research Defence Society on June 9 (*The Fight against Disease*, 26, No. 3; 1938). Prof. Best is the co-discoverer, with Prof. Banting, of the anti-diabetic substance known as 'insulin', now universally used for the treatment of the disease, and the subject of his lecture was "Insulin and Diabetes: The Present Position". The stages in the discovery and preparation of insulin were first outlined, and Prof. Best then described recent modifications—protamine- and protamine-zinc insulins—by the use of which the effect of the dose is prolonged. He next discussed the influence of insulin treatment upon diabetic mortality in Canada where since 1922 insulin has been available for everyone who wished to have it In certain age groups the mortality from diabetes is not coming down it may even be going up because there are now many more diabetics who reach the older age groups When these people die as even the diabetic must the cause of death is usually stated to be diabetes But in the earlier age groups up to fifty years diabetic mortality has markedly declined From 1891 until 1920 before the use of insulin the percentage mortality among diabetics up to 50 years of age remained steadily at about 45 per cent that is nearly half the cases died Since 1922 when insulin began to be used the mortality first steadily declined and for 1929–33 has been about 15 per cent (statistics for Ontario) This great saving of human life as well as of much suffering must be ascribed to experimental work done upon animals and Sir Edward Mellanby in proposing a vote of thanks to the lecturer bewailed the fact that it is necessary even now for scientific men to come forward and justify the use of animal experiments

Measurement of Mechanical Power

IN a lecture on the measurement of mechanical power by Dr C V Drysdale delivered to the Junior Institution of Engineers and published in its *Journal* of August he points out the urgent demand there is for the accurate measurement of mechanical power under service conditions and how impossible it is to judge the relative merit of various mechanical devices without knowledge of this and the economy of the fuel used In mercantile shipping this is fully recognized and has led to great improvements in torsion meters Many engineers are now studying the performance of aero engines especially at high altitudes and this involves the making of power measurements more especially at high altitudes during actual flight The Royal Aircraft Establishment has now designed and constructed a mechanical power (watt) meter for air screw testing Utilizing the principle that a constantly excited generator produces an electromotive force proportional to the speed and that the torque is proportional to the current it has constructed a mechanical power meter which acts satisfactorily Alternating current at a frequency of 1 500 is supplied by a small wind driven alternator on the plane Records are given which prove that accurate testing of power during flight has been accomplished Dr Drysdale states that of the millions of mechanically propelled vehicles in use it is probably safe to say that not one per cent of their engines are working with anything like their maximum efficiency One has only to watch the tuning up of an engine after decarbonization and regrinding of the valves to realize how much it depends upon the almost unaided judgment of the mechanic

The Agricultural Research Council

THE third report of the Agricultural Research Council (London H M Stationery Office 5s 6d) surveys the research work aided from State sources during the period October 1935–September 1937 Besides its co ordinating functions in respect of much of the work carried out at the various research institutes in Great Britain and its advisory capacity as regards the Development Fund the Council now possesses a field station of its own at Compton Berks where it is proposed to establish disease free herds of cattle pigs etc and to provide opportunities for experiments under scientifically controlled conditions on a larger scale than is ordinarily possible at any individual research institute The first group of experiments with cattle will be concerned with contagious abortion and will involve the testing of various vaccines Among other problems to be investigated are the causes of the unduly high death rate among pigs and poultry particular attention being paid to fowl paralysis as regards both its hereditary and its infectious aspects A new interest of the Council was marked by the setting up of an equine research committee to deal mainly with horse diseases a substantial aid for which is being provided by the Racecourse Betting Control Board The review of the research work on foot and mouth disease recently undertaken by the Council is particularly appropriate in view of the serious outbreaks this year The general conclusions are that in spite of the high cost and slow progress of the investigations they should be continued in the hope that eventually measures will be found that will make possible some modification of the slaughter policy

League of Nations Social Surveys

THE report on the work of the Advisory Committee on Social Questions of the League of Nations in 1938 (Second Session) refers to the proposed review of social questions to be published quarterly and contains in addition to information regarding the League s work on social questions special articles by experts and selected bibliographies on social questions (C 147 M 88 4 Pp 28 Geneva League of Nations London George Allen and Unwin Ltd 1s 3d) On the recommendation of a sub committee, the Committee has decided to place three new subjects on its agenda the principles adopted in the organization and administration of welfare work among the young including social assistance the training of persons engaged in social work and family desertion The first study is to be limited in the first instance, to a selected number of representative countries emphasis being placed on the study of principles adopted in organization and administration of the administrative machinery The study on training for social work will take note of the work already carried out by the International Committee on Social Service Schools in regard to the participation of universities in the training of social workers and will deal with other aspects, such as the extent to which different groups of social workers, including voluntary workers, are trained, and the training given Developments in child welfare in the past year are summarized in the report, which includes reports from the liaison officers with the International Labour Office and the Health Organisation, and formulates the broad principles arrived at from its investigations on the placing of children in families

Surveys of Town Planning

A broadsheet recently issued by Political and Economic Planning (P E P) reviews the report of the National Survey and National Planning Committee of the Town Planning Institute, the first really thorough and informed analysis of the reasons for the wasteful and undesirable development of the land which is still occurring all over England. Together with the Bressey report on the Highway Development of Greater London, it makes a major contribution to the national planning of the use of land, and as such has claims on the attention of all scientific workers who are concerned with the social problems of our technical civilization. Essentially the primary task is one of co-ordination—of fitting together the requirements of many different and often rival users of land, and where necessary choosing between them. Pointing out that there are national aspects of planning urgently requiring comprehensive study, decision and action, and that the existing planning system is quite inadequate to deal not merely with these national aspects but even effectively with the broader regional requirements, the report recommends the creation of a National Planning Commission.

The functions of this Commission would include the compilation and collation of all relevant information bearing on the use, development and planning of land from a national point of view; advising and co-ordinating Government departments, statutory undertakers and highway authorities in their use and development of land; providing planning authorities with constructive advice and guidance, such as the Minister of Health is prevented by his quasi-judicial position from providing, watching their planning operations, and making appropriate representations to the Minister of Health when necessary. The Commission would also keep the general progress of planning under review, investigate its problems, defects and delays, frame proposals for overcoming them and generally advise the Minister and the Government on the legislative and administrative development of the planning system. As a basis for its activities and as a background for local and regional planning, it would formulate a national plan or policy on broad and flexible lines for the allocation of major land uses and developments. The wisdom of this proposal is emphasized by the revelation in the Bressey report of the widespread damage being done in the absence of such measures, and the indictment it contains of recent official policy in regard to roads.

An Adolescents' Charter from Manchester

The Federal Council of Lancashire and Cheshire Teachers' Associations has recently issued a "Report on Entry into Employment" which includes a formulation in fourteen points of what the Council regards as "a working basis under the conditions at present prevailing in the industrial world and under the Acts dealing with school leaving and the regulation of factories and workshops now in force". Among the more significant of the fourteen points are: vocational guidance for all and, as a means for ensuring this, insistence on the submission at regular intervals by every juvenile advisory and choice-of-employment committee of reports to the appropriate authority (in one area 23 out of 24 such committees were found to have ceased to function); entry into employment of a school leaver to be preceded by medical examination and report, co-ordinated in each case with the child's 'health sheet'; all school planning to include 'equipment suitable for the use of older persons, and such amenities and arrangements as will appeal to the developing mind and character of the ex-pupil' (especially in rural and detached areas); continuative education for all, and *definite* arrangements to induce all school leavers to continue their education, whether in technical, commercial or art schools or in less exacting or more general courses; recreative facilities to be provided in connexion with all further education. The report dwells on the distressing waste of much of the good work done in the *primary schools owing to lack of effective means* for ensuring further education up to the point at which the adolescent attains to the will and capacity for self-instruction. In the interval between leaving the primary school and the desire to proceed further, the foundation laid in the primary school has been lost since no means or care have been taken to retain it".

The National Central Library

We read in the daily newspaper that 'the lecture system has been obsolete ever since the invention of printing". Notwithstanding, the system has led at least to the demand for public libraries. The need arose from the establishment of mechanics' institutes and the foundation of lectures for adult education. Actually the public libraries movement dates from the Select Committee of 1845, which authorized a ½*d* rate for their maintenance. The corner stone of this movement is the National Central Library, unifying and binding together, as it does, the independent units of the system. The National Central Library constitutes a central bond, through which the books in any one library are made available for use in any other. The annual report for 1937 shows that, in addition to the ten million books contained in the urban and county libraries, the National Central Library has built up gradually a supplementary reservoir of another ten million books, which may be borrowed from university libraries, and those of learned societies and similar institutions.

Commencing as an experimental library for workers' educational classes at Toynbee Hall in 1914, the Library was given a Royal Charter, as recommended by the Public Libraries Committee in 1927. This report also recommended that the Science Library at South Kensington should be the principal source on which the National Central Library should rely for the loan of books needed by students of science and that the Science Library should be made as complete as possible. Thus the National Central Library has become the centre of a national library movement, with which nearly all the public, university and other libraries in Great Britain are associated. The past year has seen the completion of a series of more self-contained regional library systems. Such a vast scheme of mutually supporting libraries must depend for its greatest efficiency on the maintenance of central catalogues. Union catalogues by authors of the books in the affiliated libraries are being compiled at various centres. The total number of entries in that at the National Central Library has reached ¾ million. A subject-catalogue of books and original articles is maintained at the Science Library and has reached 2¼ million entries. A "Union Catalogue of the Periodical Publications in the University Libraries of the British Isles" was published in 1937. The total number of books lent during that year was nearly 140,000, of which it is significant that some 400 were supplied to foreign libraries.

Prices of Biological Books in 1937

FOR twelve years the *Quarterly Review of Biology* has analysed and compared the cost to Americans of biological books, based upon the prices of all such received for review by the *Quarterly*. The analyses have produced some interesting figures regarding the relative cost of books produced by different nations, and to some of them attention has been directed in NATURE. In point of price, German books are still the most expensive, despite the announced policy of German publishers, a German average of 1·95 cents a page comparing with 1·27 for British books, and 0·85 for French. Than the last the only cheaper books published are those issued by the British Government (0·34 cents a page) and the U.S. Government (0·16), but since the last three categories are often published in paper covers, some of the saving may be on binding. Comparing 1937 with 1936, it is remarkable to find that the average price per page from every origin, except Germany and Great Britain, has been lowered —by from about 10 per cent in U.S. books to so much as 79 per cent in British Government official publications. But while the British Government has been so greatly reducing its charges, the ordinary British publishers of biological books have been compelled to increase by 16·5 per cent. However, it is possible that the particular books received by the *Quarterly* for review do not represent fair samples in every case; indeed, the total of British Government publications received in all the twelve years only amounts to 8,836 pages, so that, as the authors, Raymond Pearl and Maud DeWitt Pearl, point out, general conclusions must be drawn with caution from this material.

The First Slovakian Polytechnic

IT is true that, for a country of fifteen million inhabitants, Czechoslovakia is well provided with facilities for higher education. There are four universities, one of which is German, and numerous academies and schools of technology that grant recognized diplomas; but until now there has been no Slovak polytechnic. When the new academic year commences in October, however, this will be remedied by the opening of a polytechnic at Košice, in east Slovakia, to be named after Dr. Milan Stefaník, the Slovak astronomer who became the first Czechoslovak Minister for War. This technical institute will rank after the Comenius University of Bratislava as the second most important educational establishment in the eastern half of the Republic. The president, Dr. E. Beneš, has nominated the principal members of the staff, which will include a number of Slovaks who have graduated in science or technology. Their colleagues will be certain lecturers from the Universities and Polytechnics of Prague and Brno, and the new institute will doubtless soon be able to supply local industrial undertakings with students who have obtained their diplomas at Košice.

The Public Health of India

THE vital statistics and public health of India are dealt with in the recently published annual report of the Public Health Commissioner with the Government of India for 1935 (Vol. 1. With Appendixes. Delhi: Manager of Publications. 1937. Rs. 2, or 3*s*. 6*d*.). The mid-year estimated population was 278,199,545, the birth-rate and the death-rate per 1,000 were respectively 35 and 24, and the infantile death-rate per 1,000 live births was 164 (the corresponding rates for England and Wales are 15, 12 and 57). The total mortality from the three principal epidemic diseases—cholera, plague and smallpox—decreased by 24,000 compared with 1934, but this was more than covered by the large reduction in deaths from plague, which fell from 80,000 in 1934 to 32,000 in 1935. Cholera mortality rose to 217,000, the highest figure for the past three years. Smallpox caused 91,000 deaths, as against 84,000 in 1934. Tuberculosis is another disease the incidence of which has increased rapidly during recent years, and which is causing a heavy mortality, particularly in urbanized and industrialized areas. Of fevers, malaria caused the heavy toll of 1,632,000 deaths. No less than 150,000 women died in childbirth or from causes associated with childbirth. An account is also given of the public health services and administration, and of the work of the laboratories and institutes for medical research.

Institution of Electrical Engineers Awards

THE following scholarships have been awarded by the Institution of Electrical Engineers for 1938: *Ferranti Scholarship* (annual value £250; tenable for 2 years): L. S. Piggott (University of Oxford); *Duddell Scholarship* (annual value £150; tenable for 3 years): J. B. Higham (Penarth County School); *Silvanus Thompson Scholarship* (annual value £100, plus tuition fees; tenable for 2 years): H. Darnell (Mersey Railway Company); *Swan Memorial Scholarship* (annual value £120; tenable for 1 year): J. G. Hutton (Sunderland Technical College); *David Hughes Scholarship* (value £100; tenable for 1 year): H. E. Newton (University of Sheffield); *Salomons Scholarship* (value £100; tenable for 1 year): C. Halliday (King's College, Newcastle-on-Tyne). Grants have been made from the War Thanksgiving Education and Research Fund (No. 1) to J. W. Carroll (King's College, London), to E. Franklin (University of Birmingham), and to G. Y. Shute (University

College, Nottingham). Thorrowgood Scholarships have been awarded to C. R. Smith (London & North Eastern Railway), and E. C. Norris (Southern Railway Company).

Indian Cotton

TECHNOLOGICAL CIRCULARS Nos 323 to 338 issued by the Indian Central Cotton Committee's Technological Laboratory during the first three months of 1938 exemplify very thoroughly the work which is being done in India to improve the cotton crop of the country. Each season early samples of the crops from different parts of the country are sent to the Laboratory for test and each circular summarizes the results obtained in the last six years. No 336 deals, for example, with a pure line strain isolated in 1931 and grown at the Government Experimental Farm, Akola, where the rainfall is 28 inches per annum, the soil black cotton soil, the growing period from June until November and the maximum temperature varies from 85° to 115° F.; weight of cotton per seed, 30 milligrams, of seed, 62 mgm 26 seeds per boll, 16 to 18 bolls per plant, yield, 400–800 lb. per acre; 43 thousand acres under cultivation as against 120 acres in 1933. The average length of fibre (staple) is ⅞ inch, the curve of deviation being approximately the error curve In manufacture, the percentage of loss from dirt is low, that from carding is normal, about 8 per cent. Fibre strength was best in 1933 and then suitable for yarn of 31 counts, that is, 31 hanks of 480 yards to the pound

Butterfly Migrations in the Tropics

THE attention of travellers and residents in the tropics is directed to an attractively produced booklet entitled "Butterfly Migrations in the Tropics", recently published by the British Museum (Natural History). It is written on behalf of the Trustees of the Museum by Dr. C. B. Williams, and is well illustrated by means of five three-colour process plates of typical migrant species. The booklet is issued primarily with the object of obtaining information on the subject of migration. Very little is known relative to this problem in the tropics, and it is easy for any accurate and willing observer to assist in this matter. Instructions are given with regard to the special points upon which information is desired. The booklet may be obtained from the British Museum (Natural History), London, S.W.7, price 9*d*.

International Grassland Congress

THE report of the fourth International Grassland Congress held in Great Britain in July 1937 under the presidency of Prof. R. G. Stapledon has now been published. The volume, which consists of 486 pages, contains the full texts of all papers, both plenary and sectional, delivered to the Congress at Aberystwyth. Each is printed in English or German with a summary in the alternative language, the main items of the discussion being also included. The report can be obtained from the Joint Secretaries, Fourth International Grassland Congress, Aberystwyth, for £2, post paid. A smaller volume (pp. 87), containing abstracts in English and German of the majority of the papers delivered, is available for 5*s* post paid.

Work of the Central Midwives Board

THE report of the Central Midwives Board, recently issued, reviews the work of the Board during the year ended March 31, 1937. The Midwives Roll contained the names of 65,046 women, a net increase of 2,982 on last year's roll. During the year, only 18 midwives were dealt with by the Board under its penal powers on charges of malpraxis, negligence or misconduct, as a result of which seven names were removed from the roll. The Minister of Health approved the revised rules for training and examination, on the preparation of which the Board has been engaged for a considerable time. The two most important changes effected by the new rules are (*a*) an extension of the period of training from 6 to 12 months for State-registered general trained nurses, and from 12 to 24 months for other pupil-midwives, and (*b*) division of the course of training into two parts, each of which will be completed by an appropriate examination. An important decision during the year was the permission given to midwives to administer nitrous oxide and air to women in childbirth, under certain conditions.

Congress of Electroradiology

THE fourth annual Congress of French-speaking Electro-Radiologists will be held in Paris on October 5–8. At the opening meeting, Prof. Joliot-Curie will lecture on neutrons and artificial radio-elements—biological applications and therapeutical hypotheses. The following subjects will also be discussed. the results of radiological methods of examination; the bio-electric phenomena of the nervous system, present state of the question and possible application, anti-inflammatory roentgentherapy; biological action of rays and high-frequency currents; progress of histo-radiography, fresh data on neuro muscular stimulation, interpretation of electrotonic phenomena The subscription is 100 francs, which should be sent to Dr Morel Kahn, 45 rue Scheffer, Paris 16^e. Further information can be obtained from Dr. Delherm, 1 rue Loas Cases, Paris 7^e

Studentships and Fellowships in Medical Research

THE Medical Research Council invites applications for a third series of studentships and fellowships intended to encourage young British medical graduates towards becoming investigators in those branches of medical science which are concerned directly with disease as it occurs in human beings. Post-graduate studentships are offered for medical graduates who have already held house appointments and are strongly inclined to a career in clinical science or experimental pathology. Each selected student will receive a stipend at the rate of £200 per annum, during a period not exceeding twelve months, for personal maintenance while undertaking approved courses of study in Great Britain such as may be regarded as best calculated to advance the student's training in methods of research. The Council also offers research fellowships for candidates of similar qualifications who have already had some experience in the use of research methods. Each fellowship will be tenable for one year at the ordinary value of £250 per annum, and will be renewable in approved instances at the rate of £300 per annum for a second year Further information can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, London, S W 1

French Association of Microbiologists

ON the initiative of Profs Bordet, director of the Pasteur Institute of Belgium, Martin, director of the Pasteur Institute of Paris, and Lisbonne, of the Montpellier faculty of medicine, an association of French-speaking microbiologists was formed at a meeting held in October 1937 The first meeting of the new association will be held in October next on the occasion of the fiftieth year of the foundation of the Pasteur Institute of Paris, with Prof. Martin as president, and Drs. Lépine of the Pasteur Institute of Paris and Paul Bordet of the Pasteur Institute of Brussels as general secretaries. Further information can be obtained from Dr. Lépine, Institut Pasteur, 25 rue du Docteur Roux, Paris 15^e.

Announcements

CAPTAIN EYSTON in his motor-car *Thunderbolt* broke the world's land speed record on Bonneville Salt Flats, Utah, on August 27 Over the measured mile, the car averaged 345 49 m p h for both ways, the outward run being 347 49 m.p.h, and the return 343.51 m p h. The former record, established also by Captain Eyston in 1937, was 311 42 m p h. The *Thunderbolt* has two Rolls-Royce engines, each capable of developing up to 2,350 h p

DR T H. SANDERSON-WELLS has endowed an annual lectureship at the Middlesex Hospital Medical School on the relations between rheumatism and dietetics.

DR. WILHELM A P. SCHÜFFNER, director of the Department of Tropical Hygiene at the Royal Colonial Institute of Amsterdam, has been awarded the Gold Medal of Honour by the Hanseatic University of Hamburg.

THE College of Physicians of Philadelphia has awarded the Alvarenga Prize to Dr. Richard E. Shope, of the Rockefeller Institute for Medical Research, Princeton, N.J., for his recent researches on the etiology and epidemiology of influenza

THE twenty-seventh meeting of the Italian Society for the Advancement of Science will be held at Bologna under the presidency of the rector of the University on September 4–11.

THE twenty-fifth French Congress of Hygiene will be held at the Pasteur Institute, Paris, on October 3–8, when the following subjects will be discussed: the plan of the sanitary equipment of France; diet and public health; insurance and public health. Further information can be obtained from the General Secretary, Dr. X Leclainche, 18 rue de Tilsitt, Paris 17^e

THE sixth Congress of Physical Re-education organized by the French Society of Specialists in Medical Physical Culture will be held on September 10–12 at the Institute of Physical Education of the University of Paris with Prof. Roussy, rector of the University, as president of honour It will consist of three sections devoted respectively to science applied to physical education and medical gymnastics, the technique of re-education and social realization. Further information can be obtained from the president of the Society, M. Petat, 11 rue Racine, Montluçon, Allier, France

THE tenth Congress of the Far Eastern Association of Tropical Medicine, which meets every three years, will be held at Hanoi, Tonkin, on November 24–30, when the following subjects will be discussed: deficiency diseases, water supply, cholera, malaria, plague, tuberculosis, venereal disease, surgery, diseases common to man and animals, parasitology, and materia medica of the Far East. The official languages will be English and French. Further information can be obtained from the Organizing Committee, 6 rue de la Convention, Hanoi

THE fourth International Conference on Timber Utilization is to be held in Brussels on September 15–17. The subjects to be dealt with include tests on the strength of timber in relation to building regulations, timber and plywood for aeroplanes, shipbuilding, etc, and modern possibilities of the utilization of sawmill waste, and reports on the activities of the Department for Timber Utilization. Further information relating to the Conference can be obtained from the Secretary, Comité International du Bois, 50 rue Neuve, Brussels, Belgium

MESSRS ADLARD AND SON, LTD, have issued a useful diary for the academic year 1938–39, copies of which were presented to members of the British Association attending the recent meeting in Cambridge. It includes, against the appropriate dates, notes of the meetings of learned societies, and there is also a table showing the dates of the terms of the universities of the British Isles.

BRITISH DRUG HOUSES, LTD., have issued a descriptive leaflet dealing with synthetic lactoflavine, which they now manufacture. This substance is phosphorylated after ingestion, and then forms the prosthetic group of Warburg's yellow ferment, which probably plays an essential part in oxidations in all body cells. It cannot be synthesized in the body, and forms one constituent of the complex of substances once known as vitamin B.

Loss of Energy by Fast Particles in Nuclear Collisions

THE energy lost by a moving particle in traversing matter as the result of exciting or disintegrating atomic nuclei depends on the law of force between it and the particles constituting the nucleus, and also in general on the state of motion and of binding of the nuclear particles However, if the incident particle is fast and the forces are of short range the average energy loss in nuclear collisions may be shown to be independent of the latter factors and is the same as it would be if all the nuclear particles were free and isolated The general reason for this may be seen as follows

Let us consider a nuclear encounter in which the incident particle, velocity βc approaches the nucleus within a distance r The time of collision , τ, is then of the order of $r/\xi\beta c$, where $\xi = (1-\beta^2)^{1/2}$ Strictly speaking, terms of the order of $\lambda/2\pi\beta c$, and $\alpha/\beta c$, where λ is the de Broglie wave length, and α represents nuclear dimensions, should be added in order to avoid contradictions with the uncertainty principle and to allow for the size of the nucleus However, these terms make no significant addition and may be left out here The 'natural period , T, of a nuclear particle is of the order of δ/u, where u denotes its average velocity in the nucleus and δ represents the dimensions of the region to which it is confined (the nuclear cell in Bohr's model, for example) Now if $\tau \gg T$ the conditions are adiabatic, and the energy loss is greatly suppressed by the binding forces However, if $\tau \ll T$ we have the condition of 'sudden impulse', and the average energy loss is the same as it would be if the nuclear particles were free The transition from the one condition to the other takes place for a value, ρ, of r given by $\tau \sim T$, namely, $\rho = \xi\beta(c/u)\delta$ For the nuclear particles we may take $u/c \sim 1/5$, and for fast incident particles, such as those in cosmic rays, $\beta = 1$, $\xi \gg 1$ Thus $\rho \gg \delta$ Now δ is at least of the order of the range of nuclear forces, σ Therefore $\rho \gg \sigma$ This means that, as r increases, the interaction with the nuclear particles ceases altogether long before adiabatic conditions set in, that is, before binding forces have any effect on the average energy loss Inside the range of the interacting forces the conditions are those of a sudden impulse, and the average energy loss is accordingly the same as for a free particle

This result can also be proved by applying Born s theory of collisions in an analogous manner to its application by Bethe[1] to the excitation and ionization of atoms The result, however, holds under more general conditions than those which have to be satisfied to justify Born's approximation The application of the above arguments to the excitation and ionization of atoms leads, under the conditions of Born's approximation, to Bethe's formula for 'stopping power', and to Bohr's classical formula under the alternative conditions Of course, in the atomic problem the interaction, which is Coulombian, is to be classed as long range, and the binding forces play an essential part in limiting the energy loss

Assuming the mutual potential energy of a cosmic ray particle and a nuclear particle to be $Ve^{-b/r}$ (and using Born s approximation) the average energy lost by fast particles per centimetre in nuclear collisions, according to the above result is

$$dT/dx = (4\pi/3)NWV^2b^2/Mv^2,$$

where N is the number of nuclei per c c , W the number of protons and neutrons in the nucleus, M the mass of a proton (or neutron) and v the velocity of the incident particle which we may take as the velocity c of light With $V \sim 40$ M v , and $b \sim 1\ 0 \times 10^{-13}$ cm this formula gives an energy loss about one twentieth of that suffered in the usual collisions with the atomic electrons

The results given here differ from those obtained by Heisenberg[2] in a recent treatment of the problem though the numerical values are not of a different order of magnitude Heisenberg calculates the energy loss assuming the nuclear particles to be free, and then assumes that the effect of the nuclear binding forces is to cut out all those collisions which give an energy transfer less than the smallest excitation energy This procedure is in fact identical with that adopted in a theory of stopping power given by Henderson[3] before the advent of the new quantum mechanics and it gives results correct in order of magnitude only The energy loss calculated by Heisenberg is also greatly increased by his allowance for the initial motion of the nuclear particles in the nucleus According to my results, this motion does not contribute at all to the average energy loss though it affects its distribution The reason for this is that if a free particle with initial momentum p_0 receives in a collision momentum p, at an angle θ with p_0, the energy it acquires is proportional to $p^2 + 2pp_0 \cos\theta$ which on the average is equal to p^2 and is independent of p_0

A more detailed discussion of the points mentioned in this note will be given elsewhere

Anomaly in the Apparent Absorption of Slow Neutrons by Iodine and Boron

IN the course of some experiments on the absorption in boron of the slow neutrons (excluding those of thermal energy) which activate an iodine detector, a rather peculiar phenomenon has been noticed

It has been found that the absorption coefficient of these neutrons in boron remains apparently constant, even when some 85 per cent of the original intensity has been absorbed If, however, some 50 per cent is absorbed in an iodine filter, the boron absorption coefficient of the residual neutrons has decreased to a very marked extent This last effect has also been found by Ruben and Libby[1]. The exact figures obtained are contained in the accompanying table. The errors given are probable errors and not standard deviations.

Thickness of filter	Fraction transmitted through filter	Fraction transmitted through boron absorber	Absorption coefficient
0	1	0·60 ±0·02	0·77 ±0·07
B 0·96 gm./cm.²	0·25	0·57 ±0·04	0·83 +0·12
I 0·5 ,,	0·5	0·75 ±0·04	0·38 ±0·1
I 1·2 ,,	0·25	0·84 ±0·05	0·2 ±0·1

The first and second columns give respectively the thickness of filter used and the fraction of the intensity transmitted by them, B representing a boron filter and I an iodine one. The last two columns give data for the absorption in boron of the beam of neutrons emerging from the filter. They give respectively the fraction of the intensity transmitted through a boron absorber of 0·30 gm./cm.², and the absorption coefficient deduced from this fraction (not corrected for scattering)

These results show that whereas from the boron absorptions one can say that at least 85 per cent of the activity is due to neutrons having a uniform absorption coefficient of 0·77, the iodine filtration experiment shows that some 50 per cent of the neutrons have an absorption coefficient of almost half this, 0·38

It has also been found that when both an iodine and a boron filter are used simultaneously, the activity produced in the detector depends on the order in which the filters are placed The ratio of the activity produced when the boron filter (0·77 gm./cm.²) was followed by the iodine filter (0·84 gm./cm.²) to that produced when the iodine filter preceded the boron filter is 0·78 ± 0·03.

The first experiment has been repeated using a bromine detector in place of the iodine as the absorption regions of these elements overlap to some extent[3], but no change was observed in the boron absorption coefficient of the neutrons on passage through the iodine filter Nor was any effect observed when an arsenic filter and an arsenic detector were used instead of iodine in this experiment, although iodine and arsenic detectors show nearly equal boron absorption coefficients for slow neutrons[2,4].

In all these experiments, the source of slow neutrons used was a (Rn + Be) source placed at the centre of a wax cube of side 10 cm. The sides of the cube were screened with cadmium sheets, and the absorbers and detectors were placed against the sides of the cube.

The results of these experiments do not seem to be at all explicable unless it is assumed that the passage through one or the other of the filters has resulted in a change in energy of a considerable fraction of the neutrons detected The results could be interpreted as being due to slowing down of the higher energy neutrons by boron into the iodine resonance region. Alternatively, the effect could be due to an increase in energy of some of the neutrons on passage through the iodine, this latter being possible if some of the iodine nuclei exist in a metastable state of long life.

Further experiments are in progress, however, and a fuller account will be published elsewhere.

Scattering of Yukawa Particles by Protons

I HAVE computed the electrical interaction between the heavy electrons as introduced by Yukawa[1] and recently discussed by Kemmer, Fröhlich, Stueckelberg and others[2], using the Dirac-Proca[3] equations for particles of spin one. It was thought that such a calculation would furnish polarization effects analogous to, and yet, because of the different spin, different from the effect found by Mott[4] for the scattering of electrons. The method used was the usual Born-Dirac calculus of perturbation.

It was found that in contrast to electrons, Yukawa particles show a polarization effect even in the first approximation. This effect, perhaps not wholly unexpected due to the similarity of the Proca equations with the Maxwell equations, is caused solely by the transversal wave field; it is proportional to the square of the cosine of the angle between the plane of polarization and the plane laid through the primary and the scattered ray. The second approximation also contains polarization terms, but they are of the form similar to those found by Mott in the case of the electron.

A detailed report of the calculations will be published in the *Physical Review*.

Direct Proof of the Effect of Temperature on the Conduction Electrons of a Metal

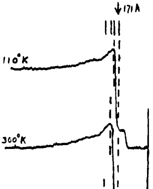
IT has been recognized for some time that the structure of the *K*-, *L*-, etc., emission spectra of the metals in the soft X-ray region (about 10–500 A.) can lead to direct information about the level system occupied by the conduction-electrons[1]. For the radiation of a metal in this region consists wholly (or, in other cases, at least partly) of a band which represents transitions of the conduction-electrons themselves into an inner shell which has been ionized by electron-impact in the X-ray tube; and since the inner level is relatively sharp, the structure of the conduction electron level system is clearly reflected in the emitted radiation. The most characteristic feature is the sharp edge which forms the short wave-length end of such a band; this evidently corresponds to the sharp 'surface' to which the conduction-electrons of the metal fill up the continuum of possible levels. But, theoretically, this surface is only sharp at the absolute zero of temperature. As is well known, the conduction-electrons are subject to Fermi-Dirac statistics and this has the result that at a temperature T, the surface is slightly diffused.

If $N(E)dE$ is the number of levels having energy between E and $E + dE$ and if $N(E)$ is assumed approximately equal to a constant N_0 in a small energy-range near the surface, then the number of *occupied* levels with energies between E and $E + dE$ at a temperature T is given by

$$n(E)dE = \frac{N_0}{1 + e^{\Delta E/kT}}\, dE \quad . \quad . \quad . \quad . \quad (1)$$

where ΔE is measured from the surface at the absolute zero[2].

We have recently been able to show that the edges of the K and L bands of metals of the first two groups are sensitive to the temperature of the anticathode of the X-ray tube from which they are emitted. The accompanying photometer curves (six times enlarged from the original plate) of the L_{23} band of aluminium at 171 A.) correspond to three anticathode temperatures. The total energy spread of the band is about 15 volts. Owing to the separation of the L_2 and L_3 levels (about 0.4 volt) the edge is actually double. Both components show a marked broadening when the anticathode temperature is changed from that of liquid air (110° K.) to 680° K., and a difference can even be detected for the change from liquid air to room temperature.



The breadth of the edge is partly due to a limitation of the resolution due to the width of the spectroscope slit, which is estimated to correspond to 0.12 volt. If this amount is subtracted from the breadth measured in the way indicated by the lines on the diagram, we obtain a corrected edge breadth; and the precise manner of measuring this quantity is such that it should correspond to about 6 kT according to equation (1), if the extra broadening is entirely due to this cause. The table below gives the results.

Temp	Corrected edge breadth (volts)	6 kT (volts)
110° K	0.06 ± 0.03	0.057
300° K	0.17 + 0.03	0.156
680° K	0.44 ± 0.05	0.354

It will be seen that, at the two lower temperatures, the breadth of the edge can be entirely accounted for according to equation (1). At the highest temperature, the breadth seems to be a little more than would be expected; the additional amount may be due to the distortion of the lattice by the large amplitude of the heat motion when the temperature of the aluminium is raised towards its melting point.

Kramers' Absorption Law in Physical Problems

IN a recent letter to NATURE[1], Dr. T. L. Page reports on an interpretation of the spectrum of hydrogen in the discharge tube and in the planetary nebulæ. The observed data consist of measures of the intensities, in emission, of various members of the Balmer series and of the continuum that lies beyond the Balmer limit. Page states: "In the nebulæ and in the discharge it can be shown that the recombination of protons and electrons must account for almost the entire emission". He interprets the data on the basis of this assumption. All the quanta of Balmer α, for example, he regards as being produced by electrons that have arrived in quantum level 3 either by direct capture in that level or by cascade from higher levels after capture. He apparently neglects all other types of excitation, such as reabsorption of the Lyman line radiation or collision. Failing to find agreement between the number of captures calculated theoretically from Kramers' well-known absorption law and the number deduced from the observations, Page concludes that Kramers' law is in error. I should prefer another alternative, namely, that the nebular and discharge spectra are not entirely due to recombination.

The number of captures in level 2 may be directly calculated from the intensity of the Balmer continuum. The number of captures in level 3 and higher are only indirectly inferred, on the basis of Page's assumption, from the intensities of the Balmer lines. According to Page's tabulation, the observed number of captures on level 3 exceeds those on level 2 by 1000 fold. A crucial experimental test of this result could be made by observing, in laboratory or observatory, the spectrum beyond the Paschen limit. I am confident that the intensity of the Paschen continuum, in either example, will not differ greatly from that of the Balmer. Thus only a small fraction of the atoms in level 3 have arrived in consequence of capture. The remainder must have arrived by collisional or by radiative excitation. The former process is likely to predominate in the electrodeless discharge. Page does not give the original observational data, but I should expect the intensities to conform rather closely to those arising from a Boltzmann distribution at the appropriate temperature.

In the nebulæ, a much better agreement is obtained by applying the full theory developed by Carroll[2] and Cillié[3]. This theory is based on the premise that the nebula is optically thick so that *all* the ultraviolet stellar radiation beyond the Lyman limit is converted, by successive absorption and emission processes, into long wave and Lyman α quanta. When the effect of the radiation field is taken into account, the discrepancy practically vanishes. At Harvard Observatory, Mr. James Baker, Mr. Lawrence Aller and I have been preparing a series of papers[4] dealing with the theoretical Balmer decrement under different physical conditions. In Cillié's calculations, the number of discrete hydrogen levels was limited to fourteen, because transition probabilities were available for only this number[5]. In the Harvard investigations no such limitation was imposed[6].

The following table[7] summarizes some of the Harvard results. The observed data, quoted from Berman[8], have been corrected for the effect of space reddening.

	5000°	40,000°	Obs.	80,000°
Hα	2.43	2.71	2.77	2.83
Hβ	1.00	1.00	1.00	1.00
Hγ	0.53	0.49	0.50	0.48
Hδ	0.33	0.29	0.26	0.27
Hε	0.223	0.179	0.18	0.169
H	0.157	0.120	0.12	0.112
H	0.11	0.085	0.09	0.078

The decrement proves to be extremely insensitive to the electron temperatures, indicated at the head of the column. Any temperature between 40,000° and 80,000° will fit the observations satisfactorily. Since the decrement proves to be very sensitive to the radiation field, an even wider range of electron temperatures may be considered. Page[9] has derived a temperature of 1000° from intensity measures of the Balmer continuum. My own independent measures[10] indicate a value at least ten times higher.

In view of the large number of implicit assumptions involved in Page's work, I feel that the outlook for eventually interpreting the nebular and laboratory spectra of hydrogen on the basis of wave mechanics is hopeful. We shall not have to abandon the useful Kramers formula, in so far as it is compatible with the more precise wave mechanical expression. Also, since I see no distinction in the present instance between 'astrophysical' and physical, I have dropped the qualifying 'astro' from the title of this letter.

Ultra-Violet Band System of Silicon Monoselenide

As a result of recent observations of band spectra of monoxides, monosulphides, monoselenides, and monotellurides of the group IV(*b*) elements, the spectroscopic investigation of this group of molecules has now reached a stage at which data are available for the ground states and one or more excited states of all the monoxides, all the monosulphides, three of the five monoselenides (namely, CSe[1], SnSe[2] and PbSe[2]) and one of the five monotellurides (namely, PbTe[2]). A recent study[3] of the related band systems enabled the character and approximate position of the corresponding system of SiSe to be predicted.

It was observed[3] that the ultra-violet system of SiS is well developed in a heavy current discharge through Al_2S_3 vapour in a silica tube. An analogous method has now been successfully employed to develop the corresponding system of SiSe. In a 2.5 amp. discharge through a silica tube containing aluminium selenide a system of some 30 bands degraded to the red has been observed in the region λ 2914–λ 3671, the 0 → 0 band being at λ 3089.3 and comparatively weak. The heads are approximately represented by

$$\nu_{\text{head}} = 32{,}448.7 + (404.3\,u' - 3.24\,u'^2) - (580.0\,u'' - 1.78\,u''^2),$$

where $u = v + \frac{1}{2}$. There can be no doubt that the system is emitted by SiSe formed by the interaction of aluminium selenide and silica at the high temperature (*c.* 1,000° C.) of the positive column tube.

The ratios of coefficients discussed in connexion with SiS[3] have values of the order of magnitude expected. Thus $I_M I_X / E_e = 19.3$, as compared with 19.4 for SiS and 20.8 for SiO, I_M and I_X being the ionization potentials of the atoms, and E_e the electronic energy of the excited molecular state (all in electron volts). Secondly, the ratio $\omega_e'/\omega_e'' = 0.697$ for SiSe, as compared with 0.683 and 0.686 for SiS and SiO. Finally, the ratio (ω_e of SiSe)/(ω_e of SiS) has the values 0.790 and 0.774 for the excited and ground states respectively, as compared with 0.778 and 0.873 respectively for (ω_e of CSe)/(ω_e of CS).

Judged by the data for related band systems in this group, the value 3.24 for $x_e'\omega_e'$ in SiSe is surprisingly large; the discrepancy is due to the existence of perturbations in one or more of the excited vibrational levels $v' = 3$, 4 and 5, and the consequent difficulty in evaluating $x_e\omega_e$ correctly. With this one exception the coefficients are of the same orders of magnitude as those of the iso-electronic molecule GeS.

Work on the corresponding system of SiTe by an analogous method is in hand.

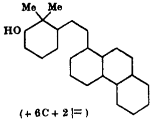
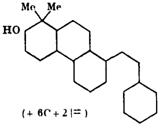
Structure of the Triterpenes

THE tetracyclic triterpene alcohol basseol, which readily cyclizes to give β-amyrenol[1], which in its turn is related to erythrodiol, gypsogenin and hederagenin[2], on dehydrogenation with selenium gives as major product a phenanthrene homologue, m.p. 125° (Found: C, 92.7; H, 7.2. $C_{17}H_{16}$ requires C, 92.7; H, 7.3; $C_{18}H_{18}$ requires C, 92.25; H, 7.75 per cent), characterized as its picrate, m.p. 165° (Found: C, 61.7, 61.8; H, 4.2, 4.3; N, 9.3. $C_{23}H_{19}O_7N_3$ requires C, 61.45; H, 4.3; N, 9.35; $C_{24}H_{21}O_7N_3$ requires C, 62.2; H, 4.6; N, 9.1 per cent). It is apparently identical with the hydrocarbon "$C_{18}H_{18}$" obtained by Ruzicka, Hösli and Ehmann[3] from hederagenin. Our analyses favour a trimethyl rather than a tetramethyl-phenanthrene formulation, but the latter cannot be excluded. The hydrocarbon gives a marked depression in melting point on admixture with 1 : 6 : 7-trimethylphenanthrene, and it is not identical with 1 2 8- or any other known trimethylphenanthrene The formation of a tri or (tetra-) methylphenanthrene shows that basseol has one of the partial structures I and II



(I)



(II)

The structure (III) suggested for basseol by Ruzicka and Schellenberg[2] cannot be correct, as this would require the formation of 1 6 dimethylphenanthrene on dehydrogenation

The identification of the dehydrogenation product, which will have a considerable bearing upon the structure of the oleanolic acid group is now in progress

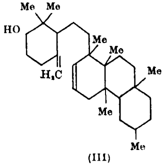
Preparation of 2 8-Diamino Acridine

IT has recently been shown[1] that amino derivatives of acridine combine high antiseptic potency with low toxicity when the orientation of the amino group(*s*) is other than the 1 (that is, 9) position Unfortunately, the general synthetic methods available for preparing specific amino acridines involve many stages and are usually wasteful of both time and material[2], so that a general reaction for converting simple aromatic compounds to amino acridines in a single operation would give valuable assistance in exploring further the chemotherapy of these compounds

A hint of the possibility of such a general reaction seems to lie in a patent of 1921 (*D R P*, 347,819) in which a mixture of glycerol, zinc chloride, *m* phenylenediamine and oxalic acid is stated to give, when heated, a 60 per cent yield of 2 8 diamino acridine, the sulphate of which is the widely used antiseptic proflavine So far, no investigation of this reaction has appeared in the literature, nor does the patent suggest that it has wider applicability

Accordingly we decided to investigate, (*a*) whether substituted *m*-phenylenediamines would take part in this reaction, (*b*) whether aniline reacted in this way either as such or when variously substituted in the *meta* position; (*c*) what the intermediate steps of the reaction are

The work has reached a stage where an interim report may be made, and our findings to date are (*a*) that a variety of substituted *meta* diamines lend themselves admirably to the production of similarly substituted amino acridines of chemotherapeutic interest, up to 72 per cent yields being obtained compared with 62 per cent yield of proflavine-base which we obtained from unsubstituted *m* phenylenediamine, (*b*) that *meta* substituted anilines are most reactive when the substituent is (in descending order of activity) NH_2 $N(CH_3)_2$, OH and least active when it is CH_3 Cl, NO_2, SO_3H or COOH (aniline itself does not react), (*c*) that the weight of experimental evidence strongly suggests in the case of *m* phenylene diamine that the final intermediate is not a diphenyl methane derivative (as would be expected from analogy with the condensations of formaldehyde with aromatic amines in the production of dihydro acridines) but 3 3 diamino N formyldiphenylamine The precursor of the latter compound may be either 3 3 diaminodiphenylamine or 3 aminoformanilide both of which were converted to amino acridines by this general reaction (in the case of 3 aminoformanilide the oxalic acid was omitted)



(III)

Sections (*a*) and (*c*) of the work are still in active progress and a detailed report will appear later

Effect of Desoxycorticosterone and its Esters

WORK carried out in our laboratories[1] has shown that the output of activity of the male and female sex hormones can be varied almost as desired by suitable esterification By subcutaneous injection of an oily solution, it can reach quite considerable values, in particular, the effect of a few days duration with the free hormone can be raised to several months by using the corresponding esters

An increase in effect in the above sense has not been observed up to the present with progesterone and its derivatives[2] It therefore seemed of interest to investigate the effect of 21 oxyprogesterone or desoxy corticosterone, the artificially prepared hormone of the adrenal cortex first synthesized by Steiger and Reichstein[3] It is known that extracts of the adrenals have only a relatively transitory effect so that, as is the case, for example, with insulin, it must be injected very frequently when used for therapeutic purposes This permits the assumption that the hormone is quickly degraded in the organism In order to solve this problem, we are occupied in preparing and investigating, in addition to the already known acetate, a series of other esters of desoxycorticosterone The accompanying table gives some preliminary results

	Melting point		Average duration of effect in days with a single injection of	
			10 mgm	20 mgm
Desoxycorticosterone	141	142	9	—
acetate	1	159°	10	12
propionate	163	164	11	—
-n butyrate	110	111		20
-n valerianate	84	85	1[illegible]	
palmitate		61	2[illegible]	
benzoate	209	210	20	—
acetate + 100 mgm palmitic acid			14	

Control animals average time of survival 6 5 days

According to the usual test method the cortical hormone is injected *daily* or even more frequently, we gave to adrenalectomized young rats immediately after the operation a *single* injection of 10 mgm and 20 mgm respectively of the substance to be tested the substance was injected subcutaneously in 2 c c of sesame oil and the period of survival ascertained The figures given in the above table correspond to the average values obtained on from 5 to 13 animals per preparation The relatively transitory effect of the free hormone and the slight difference in the period of survival compared with that of the control animals is shown by the table Although with the lower fatty acid esters the average duration of effect is only slightly increased with the palmitate it is raised to more than three weeks The benzoate is also of particular interest as its duration of effect is almost three weeks

A similar increase is obtained by adding an activator such as palmitic acid to desoxycorticosterone acetate and also by converting the desoxycorticosterone ester into an enol derivative The implantation of crystals according to Parkes[4] method appears to be of particular value The duration of effect of the butyrate after implantation of a crystal weighing 10 mgm was 25 days (4 animals)

These experiments will be continued in several fields

In conclusion it should be mentioned that, tested on the rabbit s uterus according to the method of Corner and Clauberg desoxycorticosterone acetate in doses of less than 10 mgm shows a progesterone effect

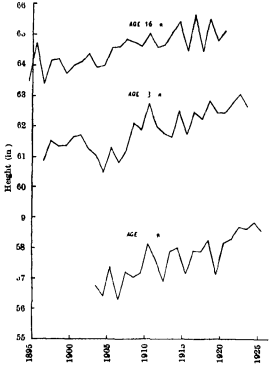
Heights and Weights in a Girls' Public School

THERE is good evidence to show that the average heights of adults have been increasing in several European countries during the past fifty years Measurements of large numbers of conscripts have been recorded, and for this period they show rates of increase which are not the same in all countries, but are all of the order 1 inch in 25 years This is an extremely rapid rate and it is clear that it cannot have been maintained for any long period in the past The statures of various populations of Europe in prehistoric and early historic times can be estimated from measurements of the long bones of series of skeletons and they do not indicate any marked departures from the averages observed to day The increase in modern times has also been observed in Japanese and Indian groups and in North American groups of European origin and it is possible that the trend has been world wide The cause of this phenomenon can only be conjectured and an explanation which attributes it to better nutrition and hygiene is not altogether satisfactory



HEIGHT GRAPH

There exist no reliable data throwing light on secular variations of the average adult statures for British populations Comparisons of the best figures available are made more difficult owing to the fact that there are clear differences between the means for different social classes More records obtained in the British Isles are available for children but the same difficulty is encountered in interpreting them *

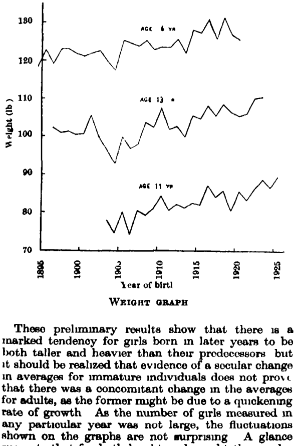
The new measurements here discussed were taken at St Paul s Girls' School at the annual medical inspections from 1907 until 1937, and were made available by the courtesy of the High Mistress Of the majority of individuals whose measurements were used, each girl participated at all three ages, so that the data are therefore more homogeneous than is generally the case If there had been a rise in the social class represented, this would diminish the significance of the results, but in fact the class level has remained almost stationary, and has certainly not risen

---

* Miss M N Karn has recently collected various records in a Summary of Results of Investigations into the Height and Weight of Children of the British Working Classes during the last Hundred Years *Annals of Eugenics* vol 7 (1937)

The figures were grouped according to year of birth and age last birthday, and the mean heights and weights of each group have been plotted on the accompanying graphs, kindly prepared by Miss Barbara Shuttleworth of Girton College

The average numbers of measurements in each group for ages eleven, thirteen and sixteen years were 34, 57 6, 63 3, respectively, and no mean is based on fewer than twenty five measurements The standard deviations for each series have also been found, and their means for the three ages are 2 682, 2 651, 2 188 in for the heights and 14 37, 17 30 15 09 lb for the weights



WEIGHT GRAPH

These preliminary results show that there is a marked tendency for girls born in later years to be both taller and heavier than their predecessors but it should be realized that evidence of a secular change in averages for immature individuals does not prove that there was a concomitant change in the averages for adults, as the former might be due to a quickening rate of growth As the number of girls measured in any particular year was not large, the fluctuations shown on the graphs are not surprising A glance suggests that for both height and weight the secular increase was greatest for the girls aged eleven and least for those aged sixteen Both sets of measurements show a fairly steady increase with time, and there is no sign of a decline in the later years or of an arrest of the movement in the case of the girls born during the Great War, although the drop for those measured towards the end of the War and immediately after (most noticeable at age thirteen) may be a reflection of war time conditions at an age at which development normally proceeds rapidly

On the assumption that the graphs for larger numbers would be close to the best fitting straight lines to the points provided by the samples available, it may be said that for the whole period the average height of girls aged eleven was increasing at the rate of about 1 in in ten years that of girls aged thirteen at the rate of about 0 7 in and that of girls aged sixteen at the rate of about 0 6 in in ten years In the case of weight the rates of increase appear to have been approximately 5 5, 4 2 and 3 8 lb, respectively, in ten years

The data presented show conclusively that the heights and weights of girls at St Paul's Girls' School have been increasing significantly in the present century Hence it is impossible to accept the view that a secular change of this kind has been confined to the lower classes of the community The fact that all grades have participated in it does not favour the theory that increasing bulk is due to improved nutrition

It is hoped to publish a fuller account of the investigation when it has been completed

I want to express my sincere thanks to Dr G M Morant of the Galton Laboratory University College London, without whose help and encouragement this work would never have been carried through

A Possible Genetic Mechanism in Heterogonic Growth of Limbs of Cattle

IT is well known that the young of most grazing mammals are born with relatively long legs fit to follow their dams To achieve these proportions limbs must exhibit *positive* heterogony[1], or allometry[2] as in the latest terminology during fœtal development, and *negative* heterogony after birth[3]

Analysing data from different sources, I investigated the course of post natal growth of fore limbs relative to the growth of the trunk in the females of six breeds of cattle, differing rather widely in birth, as well as in mature size and proportions The six breeds are the Simmentaler and the Grey Hungarian (data by Szabo v Hangai[4]), the Brown Swiss (data by Engeler[5] and by Carusi[6]), the Holstein and the Jersey (Missouri data[7]) and the Chianina (original data) I found that for all the breeds the growth of fore limbs as measured by height at withers exhibits throughout the whole or the greater part of post natal development, simple negative allometry relative to the growth of the trunk (shoulder to ischium)

The differences in size and proportions during post natal development in five out of six breeds are not at all, or at most very slightly, caused by differences in the *growth constants* α of the allometric equations $y = bx^{a}$, as α shows very close values ranging from 0 74 to 0 78 It is interesting to note that a similar fact has been observed lately by Walton and Hammond in horses[8] Therefore the breed differences must be caused chiefly by the *initial* absolute values of limb and trunk length at the moment at which growth begins to follow the post natal allometric law This moment does not occur after birth, it might occur before or, more likely, at birth

It seems possible that the genetical differentiation of the five breeds consists less of genes acting directly on post natal development than of genes determining, during fœtal development, (1) the *time* at which the post natal allometry begins to act, and (2) the *size* of trunk and limbs at this moment If this moment is not very long before birth, the conclusion might be drawn that the size of limbs and of body of the new born are not negligible factors in the size and pro portions in later life

Geographical Distribution of Zellerielles

REPORTING the occurrence of zellerielles in frogs at Capetown, Sandon[1] reviewed literature on the distribution of the genus geographically and by host families He contends that the presence of Cape zellerielles is most easily explained on the basis of former land connexions with the other southern continents Sandon noted that the American and Australian species are confined for the most part to the toothed bufonids and, following Metcalf[2], dis counted the Asiatic record of *Zelleriella macronucleata* (Bezzenberger) 1904 from *Bufo melanostictus* Nie s[3] finding of a zellerielle in *Microhyla ornata* at Nanking, however, establishes it as an Asiatic genus as well While Wenrich[4] has shown that host specificity of the Opalinidæ is much less rigid than Metcalf sup posed, the fact that in Asia (Microhylidæ) and in South Africa (Ranidæ) the host families are not toothed bufonids may be significant Further, daCunha and Penido[5] have found a *Zelleriella* in a catfish in the Paraguay River, while Carini[6] and Wenrich report others from snakes

In work on a truncate *Opalina* from *Rana boylii* of California, I have observed in the development of this species a flattened binucleate zellerielle stage, whereas a cylindrical proto opaline form is the larval type previously described as characteristic for the genus This plasticity of form in development within the multinucleate genus *Opalina* suggests that the geographical occurrence of *Zelleriella* and the diversity of its hosts may be explained by the hypothesis that zellerielles have been derived from the cosmopolitan proto opalines at various times and places

Sandon s observations on the Ranids included the statement that only one species has penetrated to North America, the Wrights[7] list twenty four species and subspecies of *Rana* for the United States

Antarctica and Glacial Ages

IN his interesting article on "Antarctica and Glacial Ages' [1], Prof MacBride states "If we add the breadth of the ice shelf to the length of the Beardmore Glacier, we arrive at a total extent of ice floe of about five hundred miles, and this is considerably longer than any glacier the existence of which we have evidence in the Pleistocene Glacial Age But, as is well known, rocks of Scandinavian origin are found in the Pleistocene glacial tills of the north east coast of Norfolk, and there seems very good reason to believe that these erratics were brought into East Anglia by ice originating in Scandinavia Thus this Pleistocene ice flow cannot have been much less than 500 miles long, and may have been considerably more Again, on p 98, Prof MacBride claims—after enumerating the Penckian glaciations, that The most interesting thing about these periods is that the bones and tools of the oldest indubitably human race are found in the inter glacial interval between the Wurm and the Reiss periods Further, on p 99 he mentions the interglacial period between the Reiss and the Wurm glaciations—the time indeed when Neanderthal man flourished I imagine that Prof MacBride is referring to the inter glacial epoch (whether it is correctly assigned to that of the Reiss–Wurm is another matter) when Late Acheulean man existed, and at the close of which the Neanderthal people lived in Western Europe and made the classic Mousterian implements Is it to these races and implements that Prof Mac Bride would confine the term indubitably human ?

It is well perhaps to remember in this regard that Neanderthal man was, to say the least of it, a very peculiar, and in several ways, simian being in his physical make up, while, more ancient in time than the Late Acheulean and Mousterian implements, are those of Lower Acheulean and Chellean times It is probable that the Lower Acheulean specimens date back to the inter glacial phase preceding that mentioned by Prof MacBride, while the Chellean artefacts are located in the deposits of the still earlier warm period—the Gunz–Mindel As both the Chellean and Lower Acheulean hand axes exhibit a skill in flaking equal to if not exceeding that of the Mousterian implements, surely the former specimens are entitled to be classed as of the indubitably human ' standard

As to whether the drift into high latitudes affords a complete explanation of all glacial phenomena previous to the Pleistocene ', I cannot express an opinion But if this drift does at last provide a complete explanation of any glacial phenomena, it will be hailed with joy by all those who are making a study of these problems For, up to the present, their explanation has been sadly lacking in completeness

J REID MOIR

Hedges,
One House Lane,
Ipswich

---

[1] NATURE 142 97 99 (July 16 1938)

I THANK Mr Reid Moir for his valuable criticism of my article "Antarctica and Glacial Ages" shall reply as briefly as possible to the two point which he raises

First, as to the size of the Pleistocene Scandinavian ice sheets, I am well aware that these sheets extended across the North Sea and that their terminal moraines form the cliffs ' of Cromer and the neighbourhood I paid two visits to Norway and in the course of the first I dredged extensively at the mouth of the Hardanger fiord and climbed to the crest of the Folgefond snowdrift 5000 ft above the sea The distance from Stavanger to Hull is about 400 miles and the origin of the Scandinavian ice flow was close to the coast where the highest ground is found But the case I put for Antarctica only included the part of it opposite South America which was explored by the Grahamstown expedition, and the highest points from which that flow originated were only 200 miles from the coast But as the diameter of Antarctica is 1,500 miles—their distance from the opposite coast must be at least 1,200 miles ! Further, since Antarctica is 7,000,000 square miles in area and the whole of it is covered by one gigantic ice sheet, it is safe to say that there is no evidence that any Pleistocene ice sheet attained anything like these dimensions

The second point which Mr Reid Moir raises is the presumed age of Neanderthal (*alias* Mousterian) man I placed him in the Reiss–Wurm interglacial interval I did so because there are no undoubted human remains from any earlier horizon The terms Chellean and Acheulean are based not on remains but on stone tools, and I am heretic enough to doubt whether the differences between these tool types represent anything more than slight changes in the same culture If we had corresponding remains I have no doubt that Chellean bones would be essentially similar to the Neanderthal type But if the Chellean tools can really be placed in the Mindel Reiss interglacial interval I am most ready to stand corrected That the first appearance of man belonged to a somewhat earlier horizon in the glacial epoch than I had imagined would make no difference to my argument

Points from Foregoing Letters

BY applying Born s theory of collisions, and also by an independent method, Dr E J Williams estimates that the energy lost by fast moving particles in nuclear collisions when traversing matter, is the same as it would be if the nuclear particles were free and isolated

Experiments by J L Michiels with slow neutrons show that they are anomalously absorbed in boron and iodine filters, and that the activity produced in the detector depends on the order in which the filters are placed The results seem to indicate either a slowing down of the higher energy neutrons by the boron into the iodine resonance region, or an increase in the energy of some of the neutrons on passage through iodine

Photometric curves of the X ray spectra of aluminium at different temperatures (110°, 300° and 680° K) are submitted by Dr H W B Skinner, showing changes in the breadth of the edge of the L_{23} band at 171 A The change between the lower temperatures can be explained by the heat effect upon the conduction-electrons, but the broadening at the higher temperature seems to imply a distortion of the lattice near the melting point

Dr D H Menzel points out an alternative interpretation of T L Page's conclusions in connexion with nebular and laboratory spectra of hydrogen, which does not invalidate Kramers absorption law

R F Barrow reports the observation and vibrational analysis of the ultra violet band system of SiSe corresponding to that of SiS recently described by him and Dr W Jevons

Further steps in the elucidation of the chemical structure of basseol, a triterpene alcohol are reported by J H Beynon, Prof I M Heilbron and Dr F S Spring who submit two possible formulæ

The reaction by which 2 8 diamino acridine is produced from *meta* phenylene diamine in a single operation has been investigated by Dr Adrien Albert and Miss Dorothy Large and found to be of general application The course of the reaction is indicated

The physiological action of desoxycorticosterone (the artificially prepared hormone of the adrenal cortex) upon rats whose adrenal glands had been removed can be prolonged by using the esterified hormone The longest effect has been obtained by Dr K Miescher Dr W H Fischer and F Tschopp by subcutaneous injection of the palmitic acid ester dissolved in sesame oil

Analysing data from various sources, Dr G Pontecorvo finds that in the females of five out of six breeds of cattle the difference in size and proportion of fore limbs relatively to the trunk in the various breeds (during post natal development) are caused chiefly by the absolute values of limbs and trunk at the moment when the growth changes from positive to negative allometry , and this occurs either before, or at, birth The genetical differentiation between breeds, he suggests may be due to genes acting upon the fœtal rather than the post natal development

J L Mohr points out that the parasitic zellerielles in frogs are more widely distributed than usually supposed, and that their sporadic geographical occurrence may be explained by the hypothesis that the zellerielles have been derived from the cosmopolitan proto opalines at various times and places

Research Items

Pre-Folsom Culture in California

OWING to lack of funds, it has been found necessary to bring to a close the excavations on the stone age site at Borax Lake, California, which were being conducted by an expedition of the Southwest Museum of Los Angeles under Mr M R Harrington This expedition, as already announced (see NATURE, 141 p 1004) had discovered stone artefacts at a depth of eight feet below implements of the Folsom type thought to be contemporary with the Folsom industry found in New Mexico in association with an ice age type of fauna, now extinct Further investigations at Borax Lake since the first announcement only serve to confirm the initial view of the high antiquity of the implements from the lower series, but the deposits are at too great a depth, and the site too vast, for complete systematic examination with the limited financial resources the museum expedition has at its disposal This would be possible only if Government assistance were forthcoming through a grant from the Public Works appropriation In the meantime, it is announced in a statement issued by Science Service of Washington, D C, certain tentative conclusions have been formed on the basis of this first season s work Presumably the Folsom people who camped at Borax Lake were of the same type as those of the Folsom sites of New Mexico and Colorado, and were their contemporaries Before the arrival of the Folsom people, the site was occupied by another race, who lived there for a sufficient length of time to build up an accumulation of more than eight feet of soil mixed with human refuse The building up of this eight feet of soil and refuse gives a minimum period of time for the oldest occupation, as the level of the Folsom culture, on the surface or near it, may have been lowered by erosion, whether by wind or by water, as is known to have happened in some of the sites examined, for example, in New Mexico Much further work on the stratification is needed before these conclusions can be regarded as in any way final

Iodides as Antidotes in Thallium Poisoning

IN the course of some investigations at the Brno Veterinary School upon the action of thallium acetate on rats, Prof O V Hykeš and Dr F A Diakov have found that iodides administered subcutaneously greatly reduce the toxic and other effects of thallium (*Biologické Spisy Vysoké Školy Zvérolékařské*, 15, pp 29–45) Six groups of rats were dieted for 32 days with an addition of 0 3 mgm of thallium acetate and then for 6 days with 0 4 mgm per hundred grams of body weight Four of the groups were given daily injections of 0 5 c c of solutions of the iodides of lithium, potassium, sodium, and magnesium containing 20 mgm iodine per c c, respectively Animals of the fifth group were treated with calcium iodide, but they soon showed signs of dermatitis due to the calcium, and they were afterwards given injections of sodium iodide The sixth group, serving as a control, were given the thallium acetate with their diet but without the iodide injections They quickly developed symptoms of acute thallium poisoning, and the acetate had to be omitted periodically from their diet A seventh control group received no chemical treatment and the animals grew normally, the females having litters All the animals treated with lithium, potassium or sodium iodide looked healthy, and increased in weight and preserved their coats Rats injected with magnesium iodide looked healthy, but had lost much hair Those of the sixth group had lost almost all hair and even the feelers were affected After 35–40 days they developed eye cataracts, but no indication of this was observed with animals subjected to iodide injection Administration of iodides is thus shown to reduce very considerably the toxicity and loss of hair due to thallium salts, and the authors conclude that this antidotal effect is brought about in a physico chemical manner It would appear that the action of thallium acetate is direct and does not pass through the endocrine or endocrine sympathetic system

Phyllopod Crustacea

PAUL MATHIAS has published a most useful general memoir entitled "Phyllopoda Biologie des Crustacées phyllopodes" (Actualités scientifiques et industrielles, 447 Paris Hermann et Cie 1937) This is a good account of the group by one who has worked at it to a considerable extent All interested in these small Crustacea should possess it General characters, conditions of life, movement, respiration, alimentation, reproduction, eggs, growth and duration of life, regeneration, enemies, uses, distribution both recent and fossil, all have their fair share of attention This is an ancient group, and some of the oldest fossils known show a structure very similar to recent forms The earliest Phyllopods are found in marine deposits, but from Cambrian times freshwater forms are well characterized The author draws largely on his individual store of knowledge, especially in experimental work, making the essay specially valuable There is a good and full bibliography

Greenkeeping Research

THE latest issue of the *Journal of the Board of Greenkeeping Research* (5, No 18, 1938 *3s 6d*) contains an article on the effects of sulphur in improving the physical condition of clay soils Results from experiments suggest that surface application of sulphur increases the porosity of heavy soil, but readers are recommended to approach the St Ives Research Station, Bingley, Yorks, for advice before making trials themselves Although compost sterilization to destroy weed seeds, eelworm, etc, has been used for some years, more efficient methods are always being sought, and an article in this number of the *Journal* describes the latest steaming and electric plants designed for this purpose Interesting accounts are also given of the problems of greenkeeping research in New Zealand and the differences between greenkeeping conditions in the United States and Great Britain Particulars are supplied of the third course of instruction for greenkeepers which it is proposed to hold in the autumn provided the demand is sufficient, and attention directed to the fact that the principal makes of mower and other implements may be inspected at the Permanent Implement Exhibition at the Station

‘Stripe’ Disease of Narcissus

AT a meeting on August 22 of Section K (Botany) of the British Association, Dr J Caldwell discussed certain aspects of this disease The disease has been recognized by growers and others for a very long time, and there is evidence that it is spreading rapidly in the field In some instances in commercial stocks every plant has been found to be infected It must be noted, however that some varieties show a high degree of tolerance to the disease, even though they are highly susceptible The varietal response to the disease differs markedly, and while the symptom complexes can be grouped into various categories, it is not possible as yet to determine beforehand which types of symptoms are to be expected in any new variety The symptoms found in plants infected with stripe’ fall into three main groups (*a*) a more or less simple mosaic characterized by the appearance of small chlorotic areas on the leaves and flower stalks of the plants, with some break in the petals and coronas of varieties with coloured flowers, (*b*) severe mosaics characterized by the occurrence of large highly chlorotic areas on the leaves, and (*c*) proliferation and overgrowth of tissue on the leaves and flower stalks as in Czarina and Weardale Perfection There is probably a fourth group in which there is marked distortion in the plants, but it is not yet clear how far this differs fundamentally from the symptoms in group (*c*) The examination of a very large number of wild species of *Narcissus* growing under natural conditions has so far yielded no evidence that any of these symptoms are found in the wild *Narcissus* (*N Pseudo Narcissus*) There is no evidence that the disease is seed borne in the cultivated varieties No vector has yet been found by any of the investigators of the disease and there is little detailed published evidence that the disease is experimentally transmissible It has been found that the juice of infected bulbs is infective after passage through Pasteur Chamberland *L*3 candles and that the agent reacts in a manner typical of a virus The method of inoculation found to be most effective was by hypodermic needle with subsequent damage to the leaf tissue at the base of the leaves In the main, inoculations made in the early part of the season are more effective than those made later The histological changes in the tissues associated with the disease are also considered

Curvature of Columnar Jointing in Volcanic Necks

THE mechanics of the columnar jointing of basaltic lava is already well understood C B Hunt has now attempted to explain the characteristic curving of such joints in volcanic necks (*Amer J Sci*, 142, 1938) The joints that first form are at the surface and stand in a vertical position The heat loss in a vertical direction from a pipe diminishes with depth, whereas the heat loss laterally diminishes inwards from the sides From an analysis of the contraction stress ratios and of the incipient fractures dependent on the variable rates of cooling, it is found that the fractures progressively change from a practically vertical position at the top to a practically horizontal position in depth At any given point, fracturing may be along either of two sets of planes, one dipping outward towards the sides of the pipe, the other dipping inward. The set dipping outward is favoured by cracks extending downward from the surface, because contraction is greater towards the sides than towards the middle of the pipe The analysis is illustrated by reference to the numerous volcanic necks of the Mount Taylor region of New Mexico (For a British example, see S I Tomkeieff The Dolerite Plug at Balleygalley Head Co Antrim" *Irish Nat J* July 1935)

Chromatographic Separation of *Cis*- and *Trans*-Azobenzene

AN interesting application of chromatographic analysis has been made recently (Zechmeister, Frehden and Jorgensen *Naturwiss* 26 495, 1938), the process having been employed for the separation of *cis* and *trans* isomerides G S Hartley (NATURE, 140 281, 1938) discovered that azobenzene (m p 68°) suffered a partial transformation into the *cis* form (m p 71°–72°) on exposure to sunlight The heterogeneity of the product can readily be shown by chromatography The solution of the mixture of the *cis* and *trans* forms of azobenzene in benzene or benzine is passed through a long tube filled with specially selected aluminium oxide Benzene is also used as developer The adsorbent shows two intense yellow zones separated by a broad white layer After elution with ice cold ether the crystalline *cis* compound was obtained, the properties of which were identical with those of the compound described by Hartley The absorption affinity of the *cis* isomeride is considerably greater than that of the *trans* form It would be possible to use the method to discover whether the spontaneous isomerization of lycopene (Zechmeister and Tuzson NATURE 141 249, 1938) is a *cis trans* isomerization

Inclination of Spiral Nebulæ to the Line of Sight

IN January 1938 Mr F G Brown published a paper in which he showed from his calculations of the inclinations to the line of sight of the planes of the extra galactic nebulæ of more than 2 in diameter in Reinmuth s catalogue that the preponderance of small inclinations could not be accounted for by observational selection but was apparently due to a systematic orientation of the planes in space (*Mon Not Roy Astro Soc* 98 3 1938) A notice of this paper appeared in NATURE of April 30 p 796 Dr. H Knox Shaw considers Mr Brown s conclusions are so inherently improbable that he felt it worth while to investigate the matter further (*Mon Not. Roy Astro Soc*, 98, 7, May 1938) He has made a calculation similar to that of Mr Brown using the objects in the Shapley Ames catalogue given in the *Harvard Annals* (88 2, 1932), but adopting the revised dimensions and descriptions for 448 of the nebulæ given in Part 4 of the same volume of the *Harvard Annals* As this catalogue covers the whole sky and the dimensions of the nebulæ contained therein are taken from a number of sources, it affords the best material for testing the matter under discussion The Heidelberg catalogue used by Brown goes down to declination −20° only and for this reason probably contains a larger proportion of nebulæ from the polar cap than the Harvard catalogue, which shows that about one third of its objects are within 30° of the north galactic pole The elongated spirals are a little more frequent in this region than elsewhere and the large proportion of elongated objects found by Brown may be due to the preponderating influence of the rich polar cap In any event, the difference between the results from the two catalogues suggests that selection has an important effect on the figures obtained, and the planes of the spirals are probably distributed in a random manner, contrary to the view advocated by Brown

The Mathematics of Experimentation

THE first morning of the British Association meeting at Cambridge saw a discussion in Section A* (Mathematics), of exceptionally wide interest to workers in experimental science The five speakers, three American and two English, had all in recent years engaged in the study of the combinatorial problems underlying modern types of experimental design, aimed at eliminating errors due to heterogeneity of material, and at founding inferences on valid tests of significance

On one side, the experimental importance of designs such as the Latin square, now widely adopted has led mathematicians to a more serious study of old problems of which the previous treatment in the mathematical literature has been discontinuous and desultory, on the other, fresh combinatorial possibilities are being explored, capable of meeting the peculiar experimental difficulties encountered in fields at present ill supplied with effective experimental designs

Prof C C Craig, of Ann Arbor, Michigan, opened the discussion with an account of tests of significance from which the customary basis of the theory of errors, the normality of residual deviations, is completely eliminated Such tests, using the ancillary information supplied by the data themselves, have been the subject of several recent mathematical papers Their logical cogency is unquestionable, but their use is limited by their being certainly laborious, and usually believed to be less sensitive than the simpler tests in common use Prof Craig exhibited a theoretical approach to the problem of sensitivity, and showed that this is more nearly comparable than is often supposed with that of the ordinary tests based on the theory of errors

In discussing the enumeration of the Latin and Græco-Latin squares of side 7, Dr Horace W Norton, of the Galton Laboratory, London, gave a most interesting account of the transformation sets into which these can be grouped As has long been recognized, an aggregate of 7! × 6! (3,628,800) Latin square solutions may be represented by a single standard square, having the letters of the first row and column in standard order By the process of intramutation, the six letters other than the corner element, *A*, are permuted, and the rows and columns rearranged to the standard order Thereby sets up to 720 standard squares may be generated, such sets having an invariant diagonal structure, by which possible identifications can be recognized Choice among the 49 possible corner elements then gives a transformation set of possibly 35,780 standard squares Finally, permutation of the three categories, rows, columns and letters, may yield 6 adjugate sets, or 211,680 standard squares in all In the less degenerate sets, recognition of possible identities among corner elements, and among categories, is easily accomplished by mapping the positions of the 2 × 2 Latin squares, of which usually, but not always, there are a number intercalated in any square under investigation These big sets are sufficiently large to be useful in enumerating the entire family of 7 × 7 Latin squares, which do not perhaps exceed 25 million in number The essence of the procedure is that we should be able to test expeditiously whether any given square is a member of a set already known, or whether a new set has been discovered

The reversal of an intercalated 2 × 2 square will generate a new square, not usually belonging to the original set Most of the sets so far known (about 100) have been discovered in this way, and it is not impossible that all sets having intercalates form one connected system The process cannot, however, lead to any set which lacks intercalates altogether, and Dr Norton made a fruitful suggestion in pointing out that reversal may also be applied to intercalated 2 × 3 rectangles, which may lead to such sets The sets lacking intercalates so far discovered are, however, all involved in Græco Latin squares, in which the permutation of four categories may generate 24 different adjugate sets having, as Latin squares, four different aspects The five known Græco Latin sets all involve in some aspect squares orthogonal to the very degenerate group known as cyclic squares, which, as Jacob had shown, are only 120 in number The number of Græco solutions of these squares, running into hundreds, contrasts strikingly with the rarity of Græco solutions among the ordinary sets of Latin squares During the year, Dr Norton has enumerated about 12 million standard squares, and has incidentally brought to light a structural system of relationship, more important perhaps for our general knowledge of Latin and higher squares, than the simple problem of complete enumeration

The bearing of such combinatorial researches on practical experimentation was well brought out by the two following speakers, Dr W J Youden, of the Boyce Thompson Institute, New York, and Mr Frank Yates, of Rothamsted Experimental Station Dr Youden discussed problems confronting the plant physiologist or plant pathologist using as experimental material the successive leaves of a number of different experimental plants He gave data to explain his experience that both the individuality of the plant and the ordinal value of the leaf very largely affect the reaction observed Precision is greatly increased if both these factors can be simultaneously eliminated, as in the Latin square The number of substances or dilutions which it is necessary to test simultaneously, is, however, often greater than the number of leaves on each plant In such cases, the elimination of plant individuality may be effected by Yates's method of incomplete randomized blocks, in which although all treatments cannot be applied to any one plant, every treatment is tested in the aggregate on the same plants with one or more complete replications of the alternative treatments In other words, every *pair* of treatments occurs equally frequently on the same plant Youden showed that this advantage may be combined, as in the Latin square, with having one complete replication at each leaf level

Those solutions of the problem of incomplete blocks, of which tables have now been published, in which the number of replications is equal to the number of elements in a block, furnish the basis for the formation of Youden's squares In these the rows and columns are equal in number to the treatments, or to the plants, while the letters are only as numerous as the number of replications, or of leaves on each plant Every row and column must contain all letters once, the remaining spaces being unoccupied Further, every pair of rows (or columns) must be occupied simultaneously in the same number of columns (or rows) When the incomplete block solution is known, little difficulty has been found in completing the square The non existence of an incomplete block solution is, however, a difficult matter to establish, and Dr Youden indicated that nearly exhaustive trials so far suggested the non existence of the (arithmetically) possible 22 × 22 square having seven letters

It was gratifying to observe that a large and predominantly mathematical audience showed the greatest interest in Dr Youden's account of practical experimental requirements, and in the variety of applications which the known solutions open up in biological material

In the short time available, Mr Yates, whose work in this field is widely known, confined himself to explaining the logical genesis of the very beautiful Lattice square, commencing from the simple, triple or multiple lattice This whole group of designs is adapted to the requirements of the plant breeder who may need to test two hundred or more varieties in a single year If the number of varieties is a perfect square, they may be cross classified in a square lattice, of which the rows and columns supply the block contents in two contrasted types of replication The block size is thus reduced to the square root of the number of varieties In a triple lattice a third type of replication is supplied by choosing for the same block varieties having the same letter of a Latin square, which may always be found Squares, the side of which is an odd number, or a multiple of 4, will also always yield a fourth type of replication, making a quadruple lattice For prime numbers, and, as appeared later in the discussion, for all powers of primes, a complete set of mutually orthogonal classifications is possible, leading, if one replication of each type is used, to one of the known solutions of the problem of randomized incomplete blocks We have, however, free choice in the topographical arrangement of the plots, and if the number of varieties is the square of an odd number, such as 11, we may halve the number of complete replications by superimposing pairs of these in a Latin square, so that six 11 × 11 squares will suffice to give equal precision to all comparisons This considerable advantage, combined with the high precision to be expected in Latin square designs, makes the scheme as attractive experimentally as it is mathematically elegant

Mr W L Stevens, of the Galton Laboratory, had a surprise in store, in the form of a demonstration of the fact that for any power of a prime a completely orthogonal square exists The converse had been asserted, on the basis of an erroneous proof by Wernicke in 1910, but the theorem had appeared to be probably true from the construction in 1936 of completely orthogonalized squares of sides 8 and 9, by Yates and Fisher respectively It was known to his associates that Mr Stevens had already established a demonstration for the square of any prime number, but the very simple generalization which he gave had only occurred to him during the week

Based on the theorem that if s is a power of a prime, a field of s symbols with the corresponding operations of addition, subtraction, multiplication and division can be defined so that the results of these operations fall within the field and are unique, we may define a Latin square by the equation

$$u_L = u_\lambda u_R + u_C \qquad u_\lambda \neq 0_C$$

where u_R, u_C and u_L designate the row, column and letter of any element, and u_λ is arbitrary apart from the restriction that it may not be zero

Assigning its $s-1$ possible values to u_λ generates $s-1$ Latin squares, and the uniqueness of the solution of the equations, regarded as simultaneous in u_R and u_C

$$u_i = u_\lambda u_R + u_C$$
$$u_j = u_\mu u_R + u_C$$

shows that the element having a given letter i in the first square, and a given letter j in the second, is uniquely determined in row and column Thus any two Latin squares of the set are orthogonal, and the whole constitutes a completely orthogonalized square

It was interesting to learn that the 9 × 9 squares obtained in this way are different from one previously given by Yates, so that for the larger squares a multiplicity of completely orthogonal solutions is to be anticipated

It is much to be regretted that the programme allowed no time for discussion We should have liked to hear the reaction of many mathematicians in the audience which remained to the end closely interested

R A FISHER

Plant Growth Substances

FOLLOWING a project first put forward in 1925, the Committee on Intellectual Cooperation of the League of Nations and the International Council of Scientific Unions have agreed to collaborate in the calling of occasional conferences on well defined fields The first of these, on the plant growth substances, or phytohormones, was held in Paris on October 1–2, 1937, under the joint auspices of the CIC and the International Union of Biological Societies

The report of the conference,* which has just been issued, contains eight contributed papers and discussion Prof Kögl (Utrecht) describes the determination of the chemical nature of auxins a and b and the isolation of biotin Dr Niels Nielsen (Copenhagen) discusses the substances promoting growth in the fungi, and the difficulties introduced by the varying abilities of organisms to synthesize different members of the group of active substances The evidence associating the formation and action of auxins with oxidative metabolism is reviewed by Prof Koningsberger (Utrecht), the phenomenon of bud inhibition and other correlations by Prof Dostál (Brno) and the relation between the phytohormones and plant tropisms by the chairman, Prof Boysen

---

* Études et Recherches sur les Phytohormones Première Réunion organisée en collaboration avec l Union Internationale des Sciences Biologiques, Paris, 1 et 2 Octobre, 1937 Pp xiv+125 (Paris Institut International de Coopération Intellectuelle)

Jensen (Copenhagen) Prof G S Avery (New London, U S A) makes a plea for the consideration of the auxins as protoplasm irritants or evocators Prof Bouillenne (Liège) discusses the action of auxins on cell division and root formation and expresses the rather surprising opinion that although promotion of cambial division and inhibition of lateral bud development occur on applying pure auxins at concentrations within the physiological range, to a variety of plants nevertheless under natural conditions the auxins do not have these effects Finally Mlle Zollikofer (Zurich) reviews the rather unsatisfactory state of the work on the effect of animal hormones on plant growth It seems unfortunate that Prof Němeč who (according to the preface) proposed the conference and who has long been active in the closely related field of regeneration should not have been present

As is natural in a field which is developing so rapidly, there are many matters of dispute and most of the papers stress points of uncertainty rather than the well established facts The very extensive material presented however makes clear how impressive has been the progress in the last few years towards an understanding of the control of growth in plants Perhaps the most interesting parts of the book are the discussions which are reported in full Naturally a conversation between half a dozen men who are really familiar with the field is of much greater value than the usual questions at a large meeting

The fact that many substances which are probably not present in plant tissues have physiological effects almost indistinguishable from those of the naturally occurring auxins raised much discussion Animal hormones present parallel cases The difficulty centred partly on nomenclature and partly on the applicability of results obtained with these synthetic substances to the interpretation of natural processes As to the former an agreement was reached according to which two groups of growth substances are distinguished (*a*) the auxins (*b*) the bios group The auxins comprise those actually present in plants (phytohormones proper) and those not present but exerting similar effects The bios group includes aneurin biotin oestrin etc known to be present in plants and a group of substances designated specific nutrients such as mesoinositol β alanine leucine and pyruvic and gluconic acids The grouping of these latter under bios a term which up to now has had a rather specific meaning seems wholly unjustified both because specific nutrients are difficult to define and because such a large and heterogeneous group of compounds is involved

Another question raised was whether the action of auxins constitutes irritability or not However this was soon found to be unprofitable for lack of a clear statement of the rather old fashioned concept of irritability or stimulus and the related one of stimulus substances (*Reizstoffe*)

At the close of the conference Prof Boysen Jensen invited the members to meet again in Copenhagen in September 1939 The success of this first venture would seem to justify further extension of these small conferences between specialists in definite fields of scientific activity

KENNETH V THIMANN

Contributions of Engineering to Physics

PROF M L E OLIPHANT of the University of Birmingham took as the subject of his evening discourse to the British Association delivered at Cambridge on August 22 the contributions of engineers more especially electrical engineers to the science of physics To cover the whole field in a single lecture would be impossible and so he confined himself to a few only of the technical contributions made by electrical engineers to physics He began by making a quotation from a dinner speech of Lord Rutherford

> For the greater part of my life I have been engaged in investigations to try to obtain a clearer idea of the relations between electricity and matter and the all important part that electrical charges play in the structure of the atoms of our material world Yet I would find it difficult to tell you what electricity is It is so fundamental an entity in Nature that explanation is impossible Yet our knowledge of the laws which electricity obeys is now so complete that we are able to predict with considerable confidence the performance of any piece of electrical machinery—provided of course it is large compared to the atom

As Prof Oliphant was a pupil of Lord Rutherford and naturally the inspiration which he gave to all who worked with him in his famous laboratory has coloured his outlook, he wisely contented himself by illustrating his lecture by examples taken from the Cavendish Laboratory and the work carried out there, going back to the time when sealing wax and string were practically the only essentials of a piece of apparatus for physical research Many physicists regret the passing of that direct simplicity of approach They recognize that the physicist can no longer be self sufficient The time is therefore ripe for a review of the situation which may help us to see how the interactions of engineering and physics may best be employed to their mutual advancement

Electrical engineering by the provision of technical equipment and facilities and by nurturing physical research in its own laboratories has made the greatest contribution to the advancement of physics Prof Oliphant pointed out that when Faraday in 1831 made fundamental experiments on the magnetic induction in an iron ring he had to make his own insulated conductors by winding laboriously twine and wire together over layers of calico

Probably the greatest contribution made by electrical engineering to the physical sciences is the provision of an abundant and steady supply of electricity for laboratory purposes Prof Oliphant recalled the time when a small gas engine used to drive a dynamo and this in turn was used to charge accumulators The supply of electricity to a class was therefore limited and the voltage drop made the experiments very difficult Rutherford used to tell of the trouble of preparing each morning a number of Grove cells and how these used often to fail badly in the course of the day's work In these days also the only voltmeter in the Cavendish Laboratory was a Cardew hot wire instrument which was very sluggish in its action and took a large current, so that in measuring the voltage of a small accumulator, great care had to be taken to prevent the accumulator being run down completely Nowadays, ammeters and voltmeters of precision are available at low prices for laboratory work This is due to the great demand for them by the wireless industry

When electricians agreed to make alternating current supply the standard many laboratories found themselves in considerable difficulties, as a steady direct current is needed for many fundamental experiments Luckily the copper oxide rectifier developed by the Westinghouse Company in the United States converts the alternating current into direct current most satisfactorily These efficient and apparently everlasting little pieces of apparatus have saved physical laboratories large sums of money and have proved of immense help The copper oxide rectifier when exposed to light is found to generate an electric current It is therefore possible to use it in photometry and for measuring the density of photographic blackening

Prof Oliphant pointed out how the work of Cockcroft, Lawrence and Kapitza has revolutionized the apparatus required for a physical laboratory With the help of the Metropolitan Vickers Electrical Co Ltd a 50 cycle 2 000 kw A C generator has been constructed the nominal rating of which is 2 000 kw but when short circuited for half a cycle develops a power of 55 000 kw Magnetic fields were generated of considerable volume under a magnetic force of 300,000 gauss Dr T E Allibone s valuable work on the problem of applying high electric potentials to evacuate insulating vessels is of great importance Before he left the Cavendish Laboratory he had succeeded in producing considerable beams of artificial β rays

Dr C R Burch of Metropolitan Vickers found that it is possible to produce by vacuum distillation of mineral oils, residual oils with very low vapour pressure These oils can be distilled unchanged in a vacuum of a fraction of a millimetre The apparatus of Cockcroft and Walton was an unqualified success and with it they showed for the first time that accelerated particles of hydrogen can penetrate the nucleus of certain atoms and produce profound changes in them This and the discovery of the neutron stimulated research into these problems all over the world

At the same time that Cockcroft and Walton were developing the high voltage method for accelerating particles Prof E O Lawrence of Berkeley, California was experimenting with indirect methods which do not require large voltages He was successful in developing the cyclotron by means of which he accelerated particles to energies corresponding with nine million volts The cyclotron has proved of immense utility to nuclear research Unfortunately it is very expensive The magnets of the cyclotrons at Liverpool and Cambridge weigh 50 tons each of which seven tons is copper and they produce a field of 19 000 gauss over a gap 90 cm in diameter

The new branches of physics are by far the most fundamental of any as they touch the ultimate constitution of matter itself They can only be attacked successfully by very highly skilled teams of workers as the number of pieces of intricate apparatus which has to function simultaneously is very large New effects are being continually observed and it is necessary to explain them and correlate them with existing knowledge

Rutherford and Geiger were able to detect and count for the first time the number of α particles emitted by a gram of radium but the method has several defects and is exceedingly difficult to apply The method now used is to amplify the current produced in a small ionization chamber by the pulse of ions due to each α particle This is heard as a loud click in a speaker attached to the amplifier

Prof Oliphant concluded by giving a quotation from Bacon frequently used by Rutherford Human knowledge and human power are co extensive for ignorance of causes prevents us from producing effects Nature can only be ruled by being obeyed for the causes which theory discovers give the rules which practice applies

Radio Exhibition, Olympia

THE annual exhibition of wireless apparatus organized by the Radio Manufacturers Association was held at Olympia on August 24 until September 3, and it was notable for such features as the replacement of the B B C Radio Theatre by a glass walled television studio in operation, the first large display of television receivers in actual operation on exhibitors stands, and the complete demonstration of sound broadcasting receivers for the first time On previous occasions the stands were supplied inside the exhibition with audio frequency programme current, so that no demonstration of the radio frequency portion of receivers could be given This year, arrangements were made for all stands to be supplied with radio frequency signals so that the various receivers could be demonstrated as a whole

On the technical side, sound broadcasting receivers appear to have settled down to fairly standard types of design, and with the steady improvement of detail which has resulted in methods of lay out and manufacture during recent years, the modern receiver is very efficient and supplies the needs of the majority of listeners The chief novel feature among this year s sets is the incorporation of some form of automatic tuning by means of which a certain number of broadcasting stations can be selected at will by operating switches on the front of the receiver To what extent this feature was really required by the listener time will tell, but it would appear to be consistent with the demands of the age and to have advantages comparable with those of the automatic telephone and the pre selector gear on motor cars The automatically tuned receiver is provided with a series of about six push buttons in addition to the usual on and off switch, by pressing one of these buttons, the receiver is automatically adjusted to receive the programme from a certain station In some cases the actual stations made available to the press button control can be altered by carrying out certain more or less simple adjustments on the receiver The manner of achieving this automatic tuning varies among the manufacturers and has called forth a considerable amount of mechanical ingenuity in some cases The methods vary from the switching in of one of a series of fixed condensers across each tuned circuit of the receiver, to the use of a motor driving the main ganged variable condenser in conjunction with an electrical method of obtaining accurate synchronism with the incoming signals In all cases, the purchaser is assured that the addition of this automatic device in no way reduces the efficiency of the receiver as a whole or affects the ability to operate it manually

On the television side, the large display of receivers in operation on the various stands demonstrated admirably that this phase of the art is now on a commercial production basis, and made the visitor prone to forget that the potential market at present is limited to those who reside within about thirty miles of Alexandra Palace It is well known that reception of television has been successfully accomplished at much greater distances, but the above represents the reliable service range at present A determined effort has been made by manufacturers to reduce the cost of television receivers to the minimum, and by the use of smaller cathode ray tubes, giving good results with a picture size of about 4½ in by 4 in, complete sound and vision receivers are now available at from a little more than twenty pounds At least one manufacturer has realized also that many listeners are already adequately provided with a normal sound broadcasting receiver, for there is now available a set for television reception only, but including the sound programme appropriate thereto One of these sets gives a satisfactory picture of size 7½ in by 6 in, and the price shows a saving of one third over that of a similar model giving all wave broadcast reception in addition to the television In many cases the previous version of the domestic television receiver giving a larger picture of size 10 in by 8 in has been retained, but it is naturally more expensive Some firms provide more elaborate equipment which, by projection on to a small cinema screen, gives a picture of the order of 24 in by 20 in in size, and this provides comfortable viewing for a score or so of persons In some cases this large picture is obtained by projection from a comparatively small image produced on the screen of a cathode ray tube of 3 in or 4 in diameter In one case, however, the scanning was carried out mechanically by special forms of mirror drum, and the satisfactory demonstration given testified to the success which has been achieved in the development of the high and low speed motor driven scanners employed in this system

The remainder of the exhibition was devoted largely to the miscellaneous components and accessories utilized by the radio receiver industry Loudspeakers and public address equipment, test and service apparatus, special condensers, switches and other components were displayed in all their variety The Post Office exhibit showed the various methods and devices adopted to mitigate the interference nuisance, and some firms displayed apparatus and devices for measuring and reducing this interference Lastly, and by no means least, that most important component, the thermionic valve, was shown still to be making steady progress in the direction of increased efficiency in meeting the varied demands now made upon it While it is perhaps regrettable that this development has resulted in an increase in the number of types of valves and also in the valve bases, some consolation is perhaps to be drawn from the fact that reductions in price of the order of 20 per cent on many types were announced by several manufacturers just prior to the opening of the exhibition R L S-R

Ascent of Mont Blanc by a Lady

'A FRENCH lady named Dangeville ascended to the summit of Mont Blanc on the 4th inst [September 1838] She quitted the valley of Chamonix on the 3rd, at an early hour in the morning, slept at the Grand Mulets, and reached her perilous destination at 12 o'clock on the 4th She remained on the summit of the mountain for about an hour, wrote some notes, and drank a health to the Count de Paris The guides by whom she was accompanied spoke in the highest terms of her courage, perseverance and presence of mind Previous to this successful trip, the feat had been accomplished by only one female, a peasant of Chamonix, who, on reaching the grand plateau became exhausted with fatigue and was carried by force to the summit Mademoiselle Dangeville on her return to the Chamonix on the morning of the 5th inst, was received with the utmost enthusiasm by the inhabitants, who proceeded to meet her, and fired salutes of cannon in honour of her exploit (Annual Register, 1838)

Lyell at the Athenæum

WRITING on September 8, 1838, to Darwin, Lyell said 'I am very glad to hear you like the Athenæum I used to make one mistake when first I went there When anxious to push on with my book, after a two hours' spell', I went there by way of a lounge and instead of that, worked my head very hard, being excited by meeting with clever people, who would often talk to me, very much to my profit, on the very subject on which I was writing, or I fell in with a Review or Magazine relating to geology Now this was all very well, but I used to forget that this ought to count for work, although nothing had been written, and that I ought consequently to give up my second 'two hours spell As your eyes are strong, you can afford to read the light articles and newspaper gossip, which I could never indulge in much with impunity'

Colours of Thin Plates

THE *Mechanic's Magazine* of September 8, 1838, contained a contribution from Charles Tomlinson (1808–1897) on Experiments and Observations on the Colours of Thin Plates" Prefacing his remarks by a note on the various modes of obtaining Newton's rings and the colours of thin plates which were generally known, he offered to scientific men some new facts Some of his experiments had been made with spirit of turpentine and balsam of Peru 'When a drop of balsam of Peru," he wrote, "is allowed to fall upon the surface of water we instantly get a magnificent display of coloured rings . on applying vapour of ether, ammonia, etc , to any part of the film, its thickness is instantly reduced, so that the colour belonging to one order of Newton's rings is instantly exchanged for the colour of one of the series above it

"A magnet seems also to have an action upon the film, the North pole tending to repel it, and the South pole to attract it."

Tomlinson, who was elected F R S in 1872, made important discoveries concerning surface tension in liquids.

Native Problems in Northern Rhodesia*

THE native question as it manifests itself in Northern Rhodesia illustrates forcibly the fallacy of applying a general proposition indiscriminately to any specific group of tribal conditions among African and more especially Bantu peoples when an attempt is made to solve the difficulties which arise out of the cultural contacts of white and black Throughout the greater part of British Africa indirect rule has now been accepted as the fundamental principle of policy in administering native affairs It was adopted in Northern Rhodesia in part by an ordinance of 1929 and more fully in an ordinance of 1936 Although it would be more than hazardous to attempt to formulate a final judgment after so brief a period of trial there are indications that any measure of success that has been achieved by the introduction of this system is of so qualified a character as to raise question whether it is fully suited to the temperament of the people and the development of their institutions

This view receives support from the recently published report by Sir Alan W Pim and Mr S Milligan on the financial and economic position in Northern Rhodesia The conditions among the native population there described are such as would certainly seem to call for a considerable modification of administrative methods in the light of a more intensive study of circumstances than they have received

It is perhaps scarcely necessary to recall that indirect rule has for its objectives first to secure that administration of the affairs of a native people should be fully in accord with native ideas and institutions and secondly to foster the development of those institutions while ensuring that the initiative and sense of responsibility which are essential to cultural advancement shall not be undermined by too great dependence upon the paternal offices of white administration Conditions in Northern Rhodesia are adverse to the attainment of both these objects Among the seventy three different tribes in the territory tribal organization has disintegrated almost completely Tribal boundaries are sometimes ill defined or have been disregarded while in some instances the paramount chief of a tribal unit lying partly within British jurisdiction himself lives outside the political boundary under another power Intermarriage has blurred tribal distinctions while some tribes form too small a unit to warrant a separate organization Yet tribal distinctions cannot be ignored even though they are confused The tribes are too heterogeneous in origin to make fusion a practicable solution Even in Barotseland it is only the political dominance of one racial group the Barotse over all the others of the Barotseland plain which has made possible the organization of a system of native rule

Further under the system of direct rule which has obtained for many years the tribesmen have lost the habit of self government the initiative and the self reliance which indirect rule demands Nor are the pecuniary inducements now offered adequate to take the place of tribal interests as incentives to the performance of the functions of tribal administration while the recently instituted native treasuries are inadequately financed Hence expenditure within the native reserves is limited and what may be regarded as public works so far as that term is appropriate to tribal conditions which have aroused the interest of the native and reconciled him in some measure to taxation elsewhere in Northern Rhodesia are ineffective as a means of stimulating participation in self rule

---

* Report of the Commission Appointed to Enquire into the Financial and Economic Position of Northern Rhodesia Pp xi+366. London H.M Stationery Office 1938) 7s net

Some of these defects might be remedied A more adequate financial provision is not beyond the bounds of possibility now that the economic position holds out hope of improvement Such a measure however involves the somewhat doubtful assumption that the disintegration of the tribal system has not gone too far and that the disinclination or disability to undertake responsibility for tribal control can be overcome It is a question whether in Northern Rhodesia geographical social and economic conditions combined with native tradition in mode of life do not demand a more drastic system of tutelage than can be exercised through a system which depends upon native institutions and trusts to a lightly regulated native culture to work out its own salvation

In Northern Rhodesia while an immense tract of land is potentially arable the amount which is naturally fertile is relatively small The native reserves are overcrowded in some parts there are no inhabitants at all while in others the density of population may rise to 60 per square mile or in fishing areas to so much as 80 per square mile The ill effects of this irregularity of distribution and overcrowding are aggravated by the native mode of life Except in Barotseland the people are not as a rule keepers of cattle They live by agriculture or by fishing The rivers and lakes are in danger of being over fished and the methods of agriculture are both destructive and wasteful Frequently shifting plots are fertilized by burning off the bush and forest This combined with the inroads on forest trees made by the unregulated demands for timber of the mines and sawmills has led to serious deterioration of the soil and forest resources of the country In parts sixty years will be required for recovery

Since agriculture rises to no more than subsistence level the imposition of taxation has forced the native to sell his one commodity—his labour This has given rise to other and no less serious problems Within Northern Rhodesia virtually the only industries employing labour in any numbers are mining and the sawmill both these industries more especially mining have encouraged the native to settle with his wife and family near his work creating a population of urbanized and detribalized individuals who are ill housed for whom the provision of educational facilities and medical attention is inadequate and for whom in short there is an almost complete lack of social services and a more serious omission towards whom there is no settled policy At the same time the labourer who seeks employment outside the territory suffers disabilities owing to the lack of a properly organized system of recruiting with provision for conservation of pay and of arrangements for transport and its cost

Of the wise and on the whole moderate recommendations of the Commission the most fundamental and far reaching is the suggestion that the native reserves should be enlarged and a Native Lands Trust created on the lines which have been followed elsewhere This measure would permit of future expansion as necessary and would interfere little if at all with any prospects of white settlement It is evident however that for a generation or more advancement must be limited to the building up of a self supporting and ultimately locally administered agricultural community

Taking all these factors into account—the lack of tribal organization the unsuitability of native culture or mode of life without stringent regulation and much training to the geographical and economic conditions of the country and the consequent lack of opportunity for the development of native culture along its own lines coupled with the dangers of urbanization—question must arise whether indirect rule undiluted provides the most suitable machinery for the prolonged period of tutelage with which the administration of native affairs would seem to be faced Reactionary as it may be in the eyes of those who whole heartedly support the introduction of indirect rule as the sanest and most advantageous system for the well being of the native of Africa—as it undoubtedly is in most instances—it is a question for serious consideration whether it would not be to the advantage of the native and of the future of Northern Rhodesia if a measure of direct control were reintroduced with a staff of white officers trained in an understanding of the institutions of backward peoples and their ways of thought whose duties in addition to supervision and discipline should include the guidance of their wards along the lines of a policy of advancement framed in accordance with their mentality and cultural outlook

The field of the Pim Commission on Northern Rhodesia being limited by its terms of reference to the financial and economic position the policy of native administration as such is not within the scope of its report Lest, however, it should be thought that the view here taken of the implication of the facts recorded by the Commission is unduly pessimistic, it may be mentioned that after these comments had been written, there came to hand a brief report of Sir Alan Pim's opening remarks in a discussion at the Royal Anthropological Institute on indirect rule in Northern Rhodesia The view of the tribal situation, as it affects administration, then taken by Sir Alan is in substantial agreement with that here expressed He appears, however, to contemplate the possibility of modifying the system in such a manner as to meet the administrative difficulties He poses four questions for the consideration of the anthropologist, in which he asks how indirect rule can best be made to subserve the ideals of native development and of modern government, in view of the rapid changes in native custom that are taking place and the mixed populations growing up in industrial areas

Sir Alan's questions are framed in terms which raise issues far wider in application than to Northern Rhodesia alone In effect, he asks for a scheme of present and future policy, affecting the whole of British Africa in which indirect rule is now applied based upon an intensive scientific study of native tribal culture and institutions Is anthropology prepared with a reply ?

Medieval Calendars

Le Nombre d'Or:
Etude de Chronologie Technique suivie du Texte de la Massa Compoti d'Alexandre de Villedieu Avec Traduction et Commentaire par W E Van Wijk Pp x + 158 + 11 plates (La Haye Martinus Nijhoff, 1936) 10 florins

ALEXANDER OF VILLEDIEU in Normandy was born at that town about 1170 , at the time of his death at some unknown date he was canon of a church at Avranches As an educator of the young he adopted an original method This consisted in reducing all rules to a metrical form which the pupil was required to commit to memory A Latin grammar the *doctrinale* of about 1199, had a great vogue and was followed by an encyclopædic work, the *ecclesiale* on the same metrical lines The "Massa Compoti", a work on the calendar, runs to 509 lines and dates from 1200

This is a passage (65–69) which has a familiar parallel in all languages

Junius, Aprilis, September necne November
terdenos numerant continuantque dies ,
praeter quos omnes uno retinent sibi plures
Sed tenet in numero viginti Februus octo,
cui, si bissextus fuerit, superadditur unus

In a note on this passage, it is mentioned that the equally familiar legend, according to which this distribution of days is due to the interference of Augustus, from motives of jealousy, with the original assignment of Julius Cæsar, has no known classical authority It is attributed to the invention of Sacrobosco

These lines (49–52) may serve as a definition of the Golden Number

Ignorans numerum qui lunae praedicat ortum
per denos nonos Domini dispertiat annos
adjungens unum quicquid superest notat illum
quando nil restat decimum nonum fore constat

It might have seemed simpler to add the unit to the remainder instead of adding it to the date

The Massa Compoti owes its importance to the fact that it contains the first mention of the *aureus numerus* which supersedes the epacts and other contrivances in earlier use for the calculation of the ecclesiastical new moon The Latin text here reproduced is based on a collation of eighteen MSS , two at Utrecht two in the Bodleian, four at Paris and the rest at Erfurt It is followed by critical notes, a French translation and a detailed commentary

This work of scholarship is preceded by a discussion of the earlier history of the problem of adapting dates defined in terms of lunar months to the Julian calendar for this is what the fixing of Easter required In a rather vague and ineffective minute addressed to Alexandria, the Nicene Council of 325 enjoined the practice of that church But the use followed at Rome depended on a luni solar cycle of 84 years which has nothing in accuracy to compensate for its inconvenient length , this continued until the sixth century at Rome, until the eighth in England, and found its last refuge in Ireland For the practice at Alexandria a conjectural reconstruction is necessary According to that offered here, the Metonic cycle of 19 years equal to 235 lunations, was adopted, embracing an alternation of eight years (long familiar to the Greeks) with eleven years The Egyptian solar calendar of civil life comprised twelve months of thirty days followed by five (or six) additional days Naturally the adaptation of the two systems to one another was a complicated business owing to these extra days unequal lunar months of 29 or 30 days and the months (embolisms) intercalated in the cycle

In spite of the recommendation of the Nicene Council two centuries elapsed before a uniform practice in fixing the date of Easter at Rome and at Alexandria was brought about This was the work of a Scythian monk Dionysius Exiguus or Denis le Petit who produced his pascal table in 525 As early as 457 Victorius had made a similar attempt which met with some acceptance elsewhere than in Rome as an improvement on the 84 year cycle But his scheme failed to reproduce the Egyptian dates of Easter The success of Denis was ultimately complete until the introduction of the Gregorian calendar For this there are two reasons He was content to make a faithful adaptation of the Egyptian system to the Julian calendar Thereby he started with a strong body of support from Alexandria But his diplomacy was fully equal to his skill in computation He quoted the authority of the Council of Nicea and if further authority were wanted he produced documents with which he may have tampered always be it understood in the interest of harmony within the Church Opponents no more scrupulous in their methods than himself were not wanting but without receiving official adoption at Rome the calendar of Dionysius came finally into universal use It was a triumph of modesty and diplomatic skill

The lunar cycle of nineteen years was so exact as to be regarded as miraculous Nevertheless it accumulates an error amounting to a day in three Julian centuries Bede was aware of this growing discrepancy but he accepted the Nicene authority as a rule of the Church He therefore constructed a perpetual calendar which differs in form from that of Dionysius but gives equivalent results The main difference is that his cycle begins in January whereas the epacts of Dionysius begin with September The Massa Compoti gives the rules followed by Dionysius and by Bede and explains the relations between the two systems it is here considered to contain the most exact description of them

While the ecclesiastical rules thus evolved and adopted served their limited purpose in securing uniform practice the departure of the actual moon from the age assigned to it in the perpetual calendar became increasingly apparent One of the earliest attempts to introduce an improvement was made by Robert Grossetete bishop of Lincoln By a gradual evolution through the works of Regiomontanus Stoeffler and others this led to the modern lunar ephemeris But this phase belongs to the history of astronomy In view of the complexities local divergences and ultimate compromises for the sake of uniformity which attached to the ecclesiastical calendar in early days it becomes difficult to see that a valid objection to a fixed Easter can be sustained on doctrinal grounds H C P

Natural Selection of Human Societies

Darwin s Theory Applied to Mankind
By Alfred Machin Pp xxiv + 284 (London New York and Toronto Longmans Green and Co Ltd 1937) 7*s* 6*d* net

IF natural selection as the regulating principle of the evolution of the innumerable kinds of animals and consequently of man be true then it must be operative in the present as in the past and will continue to act Mr Machin goes a step further and logically argues that this selection must determine the social as well as the physical life of man An understanding of the process of evolution must show man why he is what he is and also why he is a member of a society which has such a distinctive structure Mr Machin traces the following sequence in the social evolution of man

The successful fighter of men and beasts our stone age ancestor had inbred selfish instincts and self preservation led him to take safety in flight he knew only the law of force hatred to others of his own kind but knowing instinctive love in relation to his family If man in his first state lived a solitary family life for long ages there would result an ineradicable feeling of hostility towards his fellow men This solitary life is by no means universally accepted by students though strongly supported by Mr Machin When the hunting grounds were eventually fully occupied men formed societies in order to win and keep a common hunting ground a purpose that needed the co operation of intelligence and morality Certain native instincts must be overcome if a hunting tribe is to survive The brave must be willing to sacrifice himself in battle that his tribe may live he must conform to tribal rules and respect the rights of others The survival values of the first social state were that he should be a good hunter warrior and patriot good husband and parent devoted to his tribe and adopting the law of vengeance as a religious duty

No civilization can develop apart from agriculture Hunting peoples do not voluntarily depart from their accustomed mode of life and they manifest violent aversion from the drudgeries of agriculture How was that transition effected ? Mr Machin draws what he terms an inevitable deduction which is that as all ancient civilizations have been based on slavery the agricultural stage began when conquered men were made slaves and set to work in the fields Hunting peoples have in most cases some knowledge of agriculture and the women grow snatch crops of certain foods which supplement the subsistence The idea might then well have occurred to them that prisoners could be profitably employed in supplementing the labour of the women

This hypothesis does not take into account the very numerous primitive peoples who till their own gardens without slave labour and is there any reason to believe that the Danubian peasants of neolithic times were owners of slaves ? Hunters can live only in small groups but if a large auxiliary sustenance from agriculture were available this restriction on numbers would disappear Mr Machin jumps from a hunting stage to an agricultural civilization and ignores the possibility of a prolonged period of small family or local groups gradually domesticating wild plants and animals and thus forming the basis for settled societies He definitely states that Men would not become cultivators of the soil save under iron compulsion That compulsion was supplied by other men the conquering class The conquerors had to defend their property and to drive the slaves to their work

It was this new type of society agricultural societies with a dual structure of conquerors and slaves which proved to be dominant and all conquering in the evolution of mankind ultimately displacing and replacing hunters and herdsmen in all the regions of the world which were suitable for agriculture A civilized country represented a rich estate such estates attracted enemies but war and conquest did not mean the destruction of civilization it simply meant that the estate changed hands

In the solitary hunting state men were governed by their instincts but in the social hunting state these instincts had to be subordinated to the rule of a morality The conduct which made for success in organized warfare was governed by the rules and principles which constituted this morality This morality was obviously the survival value of hunting societies in a world filled with societies of that type The recognition of the common need led to the formation of public opinion which maintained the laws upheld the religions and governed the reputation values applied to individuals

When we come to civilization we see an entirely new morality The virtues inculcated are not those of war but of peace honesty industry love and righteousness are the new virtues and the instinct for revenge has to be eradicated The glory of the man who can defy pain and treat death with contempt has to be replaced by the humbler virtues of patient toil thrift frugality temperance and love By all analogy with the first morality with the history of mankind and the evolution of all life we shall at once suspect that the new morality has come into being by virtue of its survival value The general presumption must therefore be that the new rules are the product of that natural selection of the fittest which has governed all evolution The whole force of the new morality is directed to secure the continuance of peaceful prosperity in the society War appears intermittently but with most decisive effects in the life of societies and whenever war appears man falls back on the ancient morality which has always maintained its sway in its original integrity

The dual structure of civilized society at last relapsed into a simpler type where the workers themselves became the defenders and rulers of the estate all men had a natural motive for exertion in the revival of the ancient rule that all men shall enjoy the fruit of their own labours With this renewed stimulus to exertion civilized prosperity has progressed by leaps and bounds

The three great positive factors in survival are wealth honestly won and widely spent a successful and fruitful marriage patriotism Man must continually be able to repress many ancient impulses and must constantly subject himself to a series of constraints and restraints His real problem is thus how to get enough happiness to make life bearable

Nature will continue to select men in accordance with their fitness to live in the world as it is and the power to adapt their inherited nature to cope with the new problems of life Natural selection will see to it that the progress of man goes on

This mainly in his own words is the gist of Mr Machin s thesis Probably it would be generally admitted that the whole matter is more complicated than is set forth in this small book and there are other factors of an immaterial nature that are not mentioned or but barely alluded to due perhaps to a desire to keep the book as small as possible There are certain statements which need correction to take one glaring instance About 2000 B C the Aryans entered India conquered and enslaved the native races there and started a civilisation in that country (p 103) As Sir Arthur Keith points out in his foreword undue weight is given to wealth and there are other points which are open to discussion Mr Machin has written an interesting and suggestive book however which should appeal to a wide range of readers A C HADDON

Land Utilization in China

Land Utilization in China
a Study of 16 786 Farms in 168 Localities and 38 256 Farm Families in twenty two Provinces in China 1929–1933 By Prof John Lossing Buck Pp xxxii + 494 + 28 plates 21*s* net Atlas Pp xii + 146 21*s* net Statistics Pp xv + 474 42*s* net (Nanking University of Nanking London Oxford University Press 1937) 63*s* the set

A SURVEY of the use which one fifth of the world s population makes of its land must be a stupendous undertaking by any standard Where in addition there are few trustworthy statistical data to hand and where land utilization has been subjected for hundreds and in places for thousands of years to the complex influences of unrecorded history the difficulties of completing such an undertaking within reasonable time appear almost insuperable Whatever may be the ultimate judgment on the value of Prof J L Buck s survey one cannot but admire the courage with which he has carried out the work and the thoroughness with which the statistical data have been collected and sifted

The survey was planned and administered by the Department of Agricultural Economics of the University of Nanking and financed chiefly by the Institute of Pacific Relations from funds given by the Rockefeller Foundation It involved four years intensive work by a large number of specially trained observers There was a threefold purpose in the project first to train students in the methods of research in land utilization second to make available knowledge of China s agriculture for its improvement as a basis of national agricultural policies and third to make available to people in other countries certain elementary information about land utilization food and population in China The knowledge which the survey has made available is presented in map and tabular form in volumes 2 and 3 the text volume 1 attempts the essential task of synthesizing the enormous mass of collected data into a series of intelligible pictures

Probably the first of the three purposes outlined above has been the most successfully achieved The project may be regarded as an experiment in land utilization survey to test the value of the straightforward numerical and economic criteria used with considerable success in new countries like the United States under the infinitely more complex conditions obtaining in one of the oldest civilizations extant The area surveyed (about 2 000 000 square miles) is divided according to the dominant crops grown into eight agricultural areas —three in the northern Wheat Region and five in the southern Rice Region These Areas are regarded as more or less distinct entities and the agricultural social and economic data are computed for each Area separately The data were collected from a hundred farms carefully selected in each of 168 localities and relate to crop acreages and yields numbers and use of animals size of farm employment of labour prices and taxation transport and marketing facilities population nutrition and sundry indexes to the standard of living Chapters on the natural features of the Chinese landscape the climate and the soils are contributed by well known specialists in these subjects Natural regions according to soils climate etc do not generally correspond with the arbitrarily defined agricultural regions but the use of the latter as survey units has the advantage of throwing into correct perspective certain apparent anomalies in Chinese land utilization such as the extraordinarily low percentage (1 1) of farm land in grass taking the country as a whole The pasture areas in the separate regions vary however from 12 2 per cent in the Szechwan Rice Area to 0 3 per cent in the Spring Wheat Area

Similar kinds of data are commonly used in land utilization studies in the United States but it must be admitted that when applied to China they seem much less useful as indexes to anything real than when applied to the United States America is a young country the aspirations of which like those of a young man can be expressed in terms of material advancement China is very old and like an old man seeks security in its declining years rather than the amassing of wealth and the exploitation of opportunity The young West sees visions of a great and prosperous Chinese agriculture equipped with all the aids of science while the old East dreams dreams of a peace undisturbed by Occidental efficiency The young West seeks to discover how the outward show of youth might be restored to the old East but its recommendations and advice are likely to fall upon deaf ears

The difficulties which the author and his collaborators have obviously experienced in synthesizing their data and in formulating practical proposals for the improvement of agriculture indicate the inadequacy of the data for the second purpose of the survey One feels that many of the recommendations could have been made without reference to the results of the survey some recommendations for example that more attention needs to be given to proper ventilation and lighting of the interior rooms in the millions of primitive cave dwellings in the loess cliffs might have been omitted without detracting from the book s practical value The lesson—and it is a very important one—which the experience gained in this survey can teach is that land utilization studies in China should be approached from some other point of view than the economic

The pivotal point in Chinese agricultural policy must apparently always be the control of the twin demons of flood and soil erosion—the inevitable consequences of prolonged land utilization in a topographically immature country The perpetual menace of China s two mighty and turbulent rivers flowing above the densely populated plains overshadows all other questions of land utilization as current events have once again tragically demonstrated Flood and its companion famine disturb the serenity of China s old age far more than do wars and poverty Their treatment demands the skill of the engineer rather than of the economist or even of the farmer or forester for the adequate regulation of land use which is the rational basis of flood control in America is a political and social impossibility in China Prof Buck recognizes the imminent threat to China s agriculture and very existence from the unruly Hwang ho and Yangtse Rivers and by emphasizing it he fulfils the third purpose of his survey

Conservation of soil and water is given first place in the list of policies suggested by the study and might be accepted by the Chinese as an essential measure of self preservation The other policies suggested desirable as they may appear would involve the virtual westernization of China

The weakness of volume 1 is that it fails inevitably to summarize adequately the monumental collection of data presented in the atlas and statistical volume It is manifestly impossible to review the contents of the latter—nearly 500 closely printed folio pages of tables The feast presented should satisfy the hungriest statistician the atlas will equally satisfy those who prefer generalization to detail G V JACKS

Crystals, Molecules and Atoms

The Fine Structure of Matter
the Bearing of Recent Work on Crystal Structure Polarization and Line Spectra Being Vol 2 of a Comprehensive Treatise of Atomic and Molecular Structure By Dr C H Douglas Clark Part 1 X Rays and the Structure of Matter Pp xxxvi + 216 + xxxvii lxxii Part 2 Molecular Polarization Pp xxxvi + 217–458 + xxxvii + lxii Part 3 The Quantum Theory and Line Spectra Pp lxxii + 459–643 + 2 plates (London Chapman and Hall Ltd 1937–1938) 15s net each

IF one is permitted to compare the exploration of a scientific subject with that of a strange country the present work is equivalent not to the thrilling account of a polar expedition or the artistic description of Italy s attractions but roughly to a guidebook a Baedeker containing useful advice for finding one s way and many well arranged facts and data Seen from this point of view Dr Douglas Clark s work is a valuable contribution to scientific literature Its main features are extended lists of publications well ordered tables and many figures some of which are excellent

It consists of three parts each contained in a separate volume The first part deals with X Rays and the Structure of Matter the second with Molecular Polarization the third with The Quantum Theory of Line Spectra The methods of investigating crystal structures with the help of X rays are treated on 2½ pages only which shows that it would not be advisable for a beginner to use this volume as a text book But as all possible methods and the names of their inventors are mentioned with references to the literature the book can serve well as a guide for the research worker He will find statements not explanations As an example of the style this sentence may be picked out from the section on Bravais lattices

It is found that 5 cases must be distinguished within the Cubic system leading to 5 Classes The reader who wishes to know how this has been found is referred to the original papers The method of classification of the lattice structures is that suggested by Ewald and Hermann in their well known Strukturbericht The structures are described and illustrated by drawings which appeal to the intuition they represent frequently not only one cell as is usual but also a great number of neighbouring cells as for example in the case of the diamond For each type of structure there is a table containing the substances belonging to this type Chapters vii and viii give an account of the investigations on colloids amorphous substances liquids liquid crystals alloys solid solutions The last chapter reports on the relation of crystal structure to molecular constitution

The second volume is of the same character Debye s theory of molecular dipoles forms the starting point for a systematic survey of experimental investigations Theoretical ideas are mentioned formulæ quoted but not derived (with a few exceptions collected in an appendix) No objection would be taken to this procedure if the theoretical background appeared in a clear outline but this is not everywhere the case A reader not acquainted with the subject would scarcely be able to recognize the really leading ideas and leading man among the endless series of papers and names quoted The method of Baedeker to mark outstanding objects with one two or three stars according to their importance might be adopted also by scientific guide books like the present one

More serious objections must be raised against the third volume which deals with the structure of atoms They are treated from the point of view of the old quantum theory of Bohr Wave mechanics is mentioned electron waves shortly described but the whole development of quantum theory since 1925 completely neglected Even the appendix is essentially based on classical physics

In spite of a number of well ordered tables and clearly drawn figures dealing with the periodic system multiplets etc I should be reluctant to recommend the book to students lest they should get a wrong impression of the present state of the theoretical development But as the tables and figures containing experimental results are not liable to become out of date the careful work which the author has done in collecting them will bear fruit M B

Elastic Properties of Non-Ferrous Metals and Alloys

Elastic Properties of Non ferrous Metals and Alloys
Collected Data By Dr J McKeown and E D Ward (British Non ferrous Metals Research Association Research Reports Association Series No 473) Pp 35 (London British Non ferrous Metals Research Association 1938) 6s

A VERY necessary task has been undertaken by the British Non Ferrous Metals Research Association in the compilation of this report of the authors research into the large mass of published information with respect to the non ferrous metals and their alloys The wide range of technical literature over which this information is spread the incomplete nature of much of it and the lack of means of checking it have combined to make it most difficult for the designer to formulate from such sources a clear opinion as to the relative merits of these different products It is therefore of the highest value that all such data should have been subjected to a critical survey by independent specialists and accepted only when found to reach a high standard of reliability Before admitting any data the authors have insisted upon having the fullest details as to the composition of the material its condition when tested the method of its production and the degree of sensitivity of the strain measuring instruments used at the test

The information—most of it is presented in tabular form though in a few instances graphical representation has been adopted as more convenient—consists almost entirely of the results of tensile tests elastic properties derived from bending and torsion tests have not been inserted The particulars given include the composition the treatment limit of proportionality elastic limit modulus of elasticity and proof stress of altogether 219 metals and alloys while in a number of cases the values of the ultimate tensile strength and the percentage elongation have been added

The materials dealt with in this comprehensive research include copper and six groups of its alloys nickel and four alloys three groups of the light metals and alloys and finally the gold silver and platinum group metals Such an authoritative presentation of the complete elastic properties of a class of materials of rapidly increasing importance is most timely and will be greatly appreciated by reason of the reliability of all the figures given

An Introduction to Biology

By E J Hatfield Pp 540 (Oxford Clarendon Press, London Oxford University Press 1938) 6s 6d

MRS HATFIELD is the senior biology mistress in a well known London school, and it is clear from this well produced book that she knows her subject thoroughly, and also how to present it to beginners She treats the subject as one of immense value to all students and not only to those very few among students who may show promise as future professional biologists

The subject matter of the book is divided into the following parts introductory, food and its manufacture food of animals, sensitivity and co ordination, food as a source of energy excretion growth, and reproduction Now to follow out this schema the author has practically revolutionized the ordinary courses as taken by School Certificate students, and introduced numerous innovations For example she has had the courage to discard the type system This is a great help to the teacher but is an added burden to the author , yet this author has succeeded in giving us a true elementary biology Here we have no dry course divided into botany and zoology, themselves subdivided into types with a half hearted attempt now and then to show the interrelations of plant and animal but a coherent, though elementary, study of life as it should be understood Ecology, for example, is not relegated to a section at the end , but, wherever it may be mentioned it is (chiefly, as is correct, from the point of view of the physiology of form and adaptation), though a short appendix deals with certain well known habitats as a guide to field work

This book is a review of the broader concepts in biology, though the School Certificate syllabuses are substantially covered Experimental method is emphasized throughout by practical directions, and to add to the interest of the subject, man as an animal and the importance of plants and other animals to man are given full consideration

There are naturally very divergent views on the teaching of biology in schools ; but no one would deny that there is room for improvement in the present syllabuses and method Mrs Hatfield s book points the right way to substantial improvement, and there is no doubt that teachers using it would find their work more interesting yet less difficult

Organic Syntheses

an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals Vol 18 Pp v+103 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd 1938) 8s 6d net

RELIABLE methods are given in this useful volume for the preparation of a further selection of twenty nine organic compounds Each of the main structural divisions of organic chemistry is interestingly represented in the list Among the aliphatic substances are acetylenedicarboxylic acid, from fumaric acid via αβ dibromosuccinic acid , allylamine, from allyl isothiocyanate , taurine, from ethanolamine, via β-bromoethylamine hydrobromide ; and betaine hydrazide hydrochloride (Girard s reagent) The introduction of two of the less familiar elements into aromatic molecules is exemplified by the preparation of 4 4′ difluorobiphenyl, from benzidine , and of diphenyl selenide diphenylselenium dichloride and triphenylselenonium chloride starting from diazotized aniline and potassium selenide The condensation of γ phenylbutyric ester with oxalic ester, followed by cyclization, yields 3,4 dihydro 1 2 naphthalic anhydride, which is then dehydrogenated with sulphur at 230–250°, yielding 1,2 naphthalic anhydride

Another *interesting condensation is that of* benzyl cyanide with ethyl acetate the resulting α phenylacetoacetonitrile yields phenylacetone upon hydrolysis α Hydrindone (from indene), protocatechuic aldehyde (from piperonal), and *p* nitrobenzaldehyde (from *p* nitrotoluene) also figure among the aromatic substances The heterocyclic representatives include 2 acetothienone (from thiophen) phenoxthin (from phenyl ether) 2 phenylpyridine (from pyridine and phenyl lithium) and *l* histidine monohydrochloride (from blood proteins)

The subject index covers vols 10 to 18 There is also an appendix containing additions and corrections for preceding volumes In all respects this latest member of the series maintains the high standard of its predecessors J R

Animal Biology

By Prof Lorande Loss Woodruff Second edition Pp xiv+535 (New York The Macmillan Company, 1938) 16s net

HERE is a course in animal biology in which plants are considered only incidental in their relations with animals Being a study in biology, in contradistinction to the more academic zoology based on the type system as in the university elementary courses in Great Britain, function is considered predominantly, and thus plants cannot be ignored altogether Such general headings as nutrition, respiration, excretion, reproduction, co ordination origin and continuity of life, etc , show how deliberately the author has discarded the familiar type system in order to give his readers a clearer conception of animal life

More than a third of the book is devoted to the impact of animal life on other modes of life especially that of man, as exemplified by the following general headings organic adaptation descent with change, biology and human welfare, the human background A generous and fascinating account of the development of biology concludes the text This is followed by an extensive bibliography and a glossary

Most students reading for a first university examination in biology demand a comprehensive text book embracing plants and animals, and those reading zoology prefer one based, chapter for chapter, on types' But to both, the subject would be enlivened and made much more interesting if they supplemented their reading with such a book as this , and teachers of biology would find it an invaluable source of information and inspiration

Oil from Coal*

THERE is a remarkable agreement on technical points between the report of the Labour Party's Advisory Committee on Oil from Coal and that of the Falmouth Committee† The latter being an official committee doubtless had access to a great deal of important material already collated and to oral information from Government officials The Labour Party the inquiries of which were completed before the publication of the Falmouth report and to which such official assistance would not be available must have had a very arduous task in collecting and sifting so comprehensive a mass of material The conclusions are, however all the more valuable from having been arrived at independently since although we are constantly being reminded that they are not infallible there is a tendency to accept official views at their face value The general agreement between two groups with such widely different outlooks will raise the technical and economic side of the problem of producing oil from coal out of the controversial field and enable policies to be formulated in the light of established facts

Both Committees agree that the cost of making oil from coal involving as it does expensive mining and conversion costs will be greater than that of importing a product freely bestowed by Nature as a reward for drilling a simple bore hole in the ground , but both sides also express qualms as to how long such bounties may be expected to continue

A difference of outlook is evident throughout the two reports This is typified by the terms of reference, which for the Falmouth Committee were to consider and examine the various processes for the production of oil from coal and certain other materials indigenous to this country, and to report on their economic possibilities and on the advantages to be obtained by way of security of oil supplies in emergency" The Labour Party claims to have taken a wider view, and the Advisory Committee set before itself the question Is it possible, by the application of science, to convert coal into liquid form and so open up a new market for the greatest of British raw materials ?'

As was only to be expected, the two groups have very different opinions about the steps to be taken in the light of the technical knowledge now available Both however are in agreement that the present preferential duty on home produced motor spirit should be continued for a further period The Chancellor of the Exchequer has already stated that he accepts the suggestion that there should be a guaranteed minimum of 8*d* a gallon for twelve years from 1938 The inference is, therefore, that the user of motor spirit must expect a continuance of a tax on petrol of at least 8*d* a gallon

The Labour Report points out that the coal oil industry cannot be developed except under the shelter of a preference and that it closely affects national defence ' The Labour Party is not prepared to see the Exchequer losing millions of pounds of potential revenue annually unless the State possesses the controlling voice in the coal oil industry As an illustration of what should be avoided the report says We regard as most reprehensible the present arrangements by which Imperial Chemical Industries Ltd enjoying a rebate of over £1,000 000 a year from taxation, is required to disclose technical information to I G Farbenindustrie and therefore to the German Government but is under no obligation to make a similar disclosure to its own Government

The recommendations of the Labour Party include the setting up of a Coal Oil Board to operate State owned plants and to supervise other plants, and that initially, as a large scale economic experiment, there should be established one new hydrogenation plant, six plants for the synthetic process and five low temperature carbonizing plants of different types

The Labour Party has always been a great believer in the value of research, and among the Committee's recommendations is one for providing a capital sum of £250,000 for development of the fuel research organization Further, since it is considered that this organization cannot fulfil its task adequately for less than £250,000 per annum, the Report recommends that its income should be brought up to this level for a period of years These recommendations, although flattering in their implications, might well fail to yield the return anticipated Successful results in research are not to be bought by money alone, and there is a danger that over-ample funds might be applied' largely to work without imagination It seems at least not unreasonable to suggest that, before so large a sum is assigned, its purpose should be determined more precisely than can be gathered from the general expression original research into the utilization of coal

---

* Labour's Plan for Oil from Coal Pp 79 (London Labour Publications Department 1938) 1*s*

† Committee of Imperial Defence Sub Committee on Oil from Coal Report (Cmd 5665) Pp. 71 (London H.M. Stationery Office 1938) 1*s* 3*d* net See NATURE 141 632 (April 9 1938)

Neither report places much reliance on the possibilities of natural oil being found in any quantity in Great Britain but recent reports suggest that the position may have changed slightly It should be pointed out that even deposits so limited as to be almost useless for providing a continuous peace time supply might still if held for times of emergency suffice to provide heavy requirements over a limited period The present policy of oil importation does not favour refining and cracking in Great Britain but such considerations might turn the balance and stimulate the erection of refining plants These in times of peace would be worked with imported raw materials but if the necessity arose could be switched over to utilize the indigenous product

Development and Evolution*

By Prof H H Swinnerton

THOSE whose memories carry them back to student days at the end of the nineteenth century will remember how simple and straight forward the relationship between development and evolution seemed to be The development of the individual we were taught repeated the history of the race The names of Von Baer and Haeckel were in some way mixed up with all this, but we were not very clear what their respective contributions were The difference between them is now much more clearly appreciated and finds expression in a tendency towards the division of thinkers into separate camps On one hand there are those who may be described as the lineal descendants of Von Baer who propounded the view that the young stages in the development of an animal are not like the adult stages of other animals lower down the scale but are like the young stages of those animals On the other hand there are the corresponding descendants of Haeckel who maintained that the adult stages of the ancestors are repeated during the development of the descendants but are crowded back into the earlier stages of ontogeny therefore making the latter an abbreviated repetition of Phylogeny (v de Beer) This is frequently referred to as the Theory of Recapitulation

Year by year students of fossils have discovered an increasing body of facts which seem to them to fit in with and give support to Haeckel s theory of recapitulation Meanwhile students of living forms have as the result of new as well as old methods of inquiry accumulated much additional evidence which seems to give the lie to this principle Thus Garstang whose survey of this field from the biological point of view has proved most helpful wrote in 1921 The idea that form changes in ontogeny were preceded by similar changes in adult ancestry is an illusion A few years later (1929) he reiterated the same opinion in a yet more forceful way saying the theory of adult recapitulation is dead and need no longer limit and warp us in the study of Phylogeny

It should be observed here that the bone of contention is not represented by the word recapitulation but by the word adult

The idea of recapitulation in the sense of summing up is also inherent in Von Baer s as well as in Haeckel s positions The fundamental difference between them and their philosophical descendants is that for the former it is a recapitulation of *juvenile* conditions for the latter it is a recapitulation of *adult* conditions

The main point at issue therefore is whether or no *adult* recapitulation either specific or general does occur

Any consideration of the relationship of development to evolution must deal with the subject from two aspects namely *retrospective* and *prospective* On one hand it must inquire whether the evolutionary changes of the past are reflected in development and if so to what extent On the other hand it must also inquire whether future evolutionary changes of sudden or of sequential character are foreshadowed in development These two aspects are of course very closely interwoven with one another in the developmental record and much confusion which has crept into discussion in recent years is due to a want of appreciation of their fundamental distinctness

RETROSPECTIVE ASPECT

In one form or another the retrospective aspect of the problem of the relationship of development to evolution has attracted the attention of embryologists even in the earliest stages in the growth of their science This is exemplified by the principles enunciated by Von Baer and Haeckel even though the former dates back to the pre-evolution age of biology

---

* From the presidential address to Section C (Geology) of the British Association delivered at Cambridge on August 22

THE EVIDENCE OF *ZAPHRENTIS DELANOUEI*

We may proceed to lay a stable foundation for our subsequent thinking by making a detailed analysis of a well established evolutionary series For this purpose no better example can be taken than that provided by the work of R G Carruthers (1910) upon *Zaphrentis delanouei*

This example has the great initial advantage that it nearly fulfils all the requirements of first class evidence In the first place it is based upon a large number of specimens which though they exhibit a wide range of forms make up a continuous series From these Carruthers selected samples typical of various phases in the sequence and called them *Z delanouei* (*s str*) *Z parallela* *Z constricta* *Z disjuncta* (early typical and advanced) respectively Between these types there occurred every gradation of form In the next place these specimens were collected from a succession of known horizons in the Lower Carboniferous rocks of Scotland Though some of these horizons were separated by relatively wide intervals the range of variation exhibited by the specimens collected at different levels overlapped to such an extent that the continuity in the sequence of forms from the bottom to the top was not broken Further the frequency of occurrence of each of the types was recorded and when plotted produced a curve which conformed to the normal unimodal frequency distribution curve When the curves for successive levels were compared it was found that the mode shifted with the passage of time from *Z delanouei* (*s str*) at the bottom to advanced forms of *Z disjuncta* at the top thus showing that the stock was undergoing a corresponding evolutionary change during the period of its existence The evolutionary character of this sequence was further supported by the very close similarity of the developmental stages of the later to those of the earlier types

On examining the development of the individuals representative of the stages in the phylogeny of the *Z delanouei Z disjuncta* gens it at once becomes obvious that the penultimate stage in the growth of *Z parallela* bears a much closer resemblance to the adult of the ancestral species *Z delanouei* (*s str*) than it does to the adult of *Z parallela* In like manner the penultimate stage in the development of *Z constricta* repeats the sum total of the characteristics which distinguish the adult ancestor *Z parallela* whilst the antepenultimate stage exhibits a similarly close resemblance to the ancestral adult *Z delanouei* (*s str*) Here then is an example which fulfils almost if not quite perfectly the requirements of the test imposed by Garstang and proves beyond dispute that specific recapitulation of adult characters does in some circumstances actually take place

Turning now to the later stages in the evolution of this gens it may be observed that two tendencies only faintly indicated in the earlier stages now become more openly manifested One is the tendency towards the establishment of radial symmetry This is expressed feebly in *Z parallela* and more clearly in *Z constricta* by the central narrowing and peripheral widening of the fossula In those later stages which are referred to as *Z disjuncta* a second tendency is rapidly expressed in the shortening of the septa and their withdrawal from the centre a tendency which in the earlier members of the gens had affected only the cardinal septum These tendencies are exhibited in progressive degrees of advancement not only in the late life of successive adult stages but they also pass back into the penultimate and eventually into the antepenultimate developmental stages of the typical and later forms of *Z disjuncta* Thus the principle of specific recapitulation of adult characters holds good also for these two new tendencies

In addition to being new these two tendencies are also out of accord with and may involve a complete reversal and suppression of earlier tendencies Thus the assumption of radial symmetry implies the disappearance of the tetrameral symmetry so characteristic of the typical *Zaphrentis* whilst the shortening of the septa is the reverse of the process of elongation by which each septum in early phases both of development and evolution attained the centre of the coral Thus it comes about that in the later members of the gens there is as it were a conflict between these earlier and later discordant tendencies with the result that the antepenultimate stages exhibit a mixed combination of features made up of the long cardinal of *Z delanouei* (*s str*) the elongated septa of *Z constricta* and the radial arrangement of *Z disjuncta* In these stages therefore there is merely a recapitulation of some of the individual features but not a recapitulation of the combination of features of the adult of any preceding generation It becomes advisable therefore to distinguish between *complete recapitulation* of the whole or part of the adult combination and the *limited recapitulation* of only isolated adult features

Re examination of Mr Carruthers s material however reveals the fact that in the development of the typical *Z disjuncta* a much earlier stage showed only six septa but these were arranged in an almost perfectly radial manner Though the corresponding stage in the other members of this gens was not forthcoming in the material discussed above it has been recognized by other workers in the earliest stages of development not only of other species of *Zaphrentis* but also in other palæozoic genera namely *Lophophyllum* *Cyathaxonia* *Dibunophyllum* *Cyclophyllum* *Streptelasma* *Syringaxon* Duerden sums up his investigations by saying The rugose corals and the zoanthid actinians have both a primary hexamerism

The embryo in this case appears therefore to retain features characteristic only of the embryonic stages in the development of other members of the phylum for as yet no adult coral of earlier date is known to possess them The examination of this very young stage in the development of *Z disjuncta* therefore furnishes confirmation of Von Baer s principle

No doubt in the development of *Zaphrentis* there were as in other Cœlentera yet earlier stages starting with the fertilized egg and passing on to a free swimming larva which of necessity are beyond the ken of the palæontologist Keeping these in mind as well as those discussed above we may distinguish in the life history of this as indeed of other organisms two main phases in development the embryonic and the neanic respectively The former covers a series of changes leading up from a single cell to a condition which has little or no resemblance to the adult but which nevertheless provides the basis out of which the adult may be produced The latter covers that series of changes in the course of which the features which characterize the adult gradually emerge and ultimately attain full expression

In the embryonic phase the combination of characters seems to have attained a state of stability that furnishes a plan of structure which is common to widely separated members of the class It must be regarded as the culmination of a long process of evolution of embryos in which many factors which concerned adult life have played no part but in which factors foundational to adult development have been preserved

In the neanic phase the organism exhibits a combination of less stable characters superposed upon the stable embryonic foundation These undergo with comparative rapidity a course of evolution the stages of which are very completely recapitulated during development The fact must be emphasized that in so far as specific and complete adult recapitulation takes place it seems in the example before us to be limited to the neanic phase

In the controversy briefly referred to at the outset biologists in discussing the problems before us, have based their arguments almost entirely upon embryonic larval or fœtal material Palæontologists on the other hand have rarely had such material at their disposal for such early developmental stages are either not capable of preservation in the fossil state or they are such minute and delicate objects as the prodissoconchs of lamellibranchs the protoconchs of gastropods and cephalopods the protaspids of trilobites which are easily destroyed The palæontologist s evidence therefore is usually drawn from neanic stages which it may be noted make up the major portion of the individual life history and are more abundantly preserved in the fossil stage Inasmuch therefore as these two classes of workers are on the whole dealing with different portions of that life history their observations and the conclusions they draw are not contradictory but supplementary As far as our study of *Zaphrentis* takes us we may say that the embryonic stages of development recapitulate the changes exhibited by corresponding stages of other forms belonging to the same general stock and that the neanic stages recapitulate the adult condition exhibited by the preceding members of the gens to which the species belongs Further within the neanic stages the principle of acceleration or tachygenesis is perfectly exemplified but its action so far as the adult combination of features is concerned does not penetrate back into the transitional and embryonic stages In these latter the rate of acceleration does not remain the same for all features and consequently the adult combination undergoes disruption

In the series *Z delanouei* (*s str*) *Z constricta* the development of the later members runs parallel to but overlaps beyond that of the earlier But with *Z disjuncta* new tendencies enter and though the earlier typical and later members of this species exhibit in their development a like parallelism and overlapping the direction they follow diverges from that of the former members of the gens By acceleration these new tendencies ultimately cut out the older combination almost completely from the developmental record of the advanced members of *Z disjuncta* Here then is a very clear case of skipping of stages or lipopalingenesis of the kind referred to by Trueman as a straightening of ontogeny as opposed to mere shortening of ontogeny which results from tachygenesis It should be noted that in this case the straightening is rendered necessary by the fact that divergent changes had previously set in

(Other examples of the same type of evidence proving the frequent occurrence of adult recapitulation were quoted from various phyla Evidence of a different type was also taken from the development of colonial organisms and from the phenomena described by Jackson as localized stages in development)

PROSPECTIVE ASPECT

Turning now to the prospective aspect of our problem we must inquire into the ways in which evolutionary changes may be foreshadowed during development Though Haeckel s main emphasis was upon recapitulation he realized that certain factors were at work which tended to vitiate the developmental record Among these was the appearance in larvæ and embryos of features which were adaptations to the conditions under which these immature organisms lived He crystallized his observations by introducing the term cœnogenesis for this phenomenon and by distinguishing a cœnogenetic stage in development which he regarded as having no recapitulatory and therefore no phylogenetic significance

Some cœnogenetic characters and the evolutionary changes they undergo are confined wholly to early development and apparently exert no appreciable direct influence upon the later stages This point was indeed stressed by Garstang for certain adaptations to motile life exhibited by larvæ Of these he says the modification of the larva in this way need not affect the organization of the adult

Fossil examples are perhaps less easily demonstrated One clear case however may be quoted from among the ammonoids in which the protoconch underwent evolutionary changes which do not appear to have influenced the later developmental and evolutionary course in any way

Some cœnogenetic characters may possibly have exerted a radical influence upon subsequent growth and evolution though they themselves have undergone no change since their first appearance An outstanding example of this has been claimed by Garstang (1928) from among the gastropods In some of these whilst the organism is still embryonic the visceral hump with its shell rotates rapidly in relation to the rest of the body through nearly 180° in only a few hours but the twisted condition remains throughout life and exerts a marked influence upon the adult anatomy

Consideration of some well known facts among fossils brings to light other possible examples of the cœnogenetic origin of new characters which have influenced subsequent history Thus in the oysters and in forms derived from them the process of cementation of the shell to other objects is confined to early life It must in all probability have originated at about the close of the embryonic phase and remained with varying degrees of persistence into early stages of the neanic phase but rarely if ever into later life Here as with the torsion of the visceral hump of the gastropod the change was cœnogenetic but it has brought in its train or opened the way for series of other changes such as the marked variability of form in the oysters and various degrees of coiling in *Gryphæa* and *Exogyra*

Recently Schindewolf in Germany and Spath in England have done good service by emphasizing the existence of palæontological evidence for characters appearing cœnogenetically and extending in subsequent generations through later stages into the adult In 1925 Schindewolf proposed the term proterogenesis for this principle of ontogenetic anticipation In 1933 he wrote a fuller account of the principle and furnished a number of examples of his own as well as from other writers

The simplest clearest and at the same time the most fully authenticated example which Schindewolf describes is yielded by fossils from the Ordovician rocks of the Scandinavian Baltic belonging to the nautiloid family of the Lituitidæ The central genus *Lituites* is characterized by the fact that while the major portion of the shell is straight the early formed portion is coiled On the basis of the principle of recapitulation it has usually been assumed that *Lituites* was the retrogressive descendant of a completely coiled ancestor Schindewolf however describes a series of forms which commences in the Vaginaten Kalk with the genus *Rhynchorthoceras* in which the shell is wholly straight or only slightly curved This is followed in the Platyurus Kalk by a variety of forms including *Lituites* itself which exhibit various degrees of coiling The series ends in the Chiron Kalk in *Cyclolituites* in which the shell is almost completely coiled

There is no need to describe specific examples of the appearance of new characters towards the end of life (deuterogenesis) in detail since every case of recapitulation looked at prospectively provides all that is required

There is a possible third mode of appearance of new characters namely mutation in the de Vriesian sense Certain fossil evidence suggests the simultaneous appearance of a variety of forms In this case however the forms may be capable of arrangement in a continuous evolutionary sense with the passage of time successive members of the series may be eliminated and thus a false impression of progressive evolution is produced Though for the sake of clearness in thinking the various developmental processes have been considered separately Evidence is forthcoming that two or more of these processes may proceed simultaneously in one and the same organism

Metallic Compounds of Protein

By Prof Fritz Lieben, Vienna

THE experiments of which an account is given below were all made in co operation with Dr Hans Jesserer in the Institute for Medical Chemistry University of Vienna The work has been based upon the study of the biuret reaction of proteins which has been known since 1833 thus all the experiments have been carried out in an *alkaline medium* and it is to the latter alone that our results apply

If a 20 per cent solution of copper sulphate is added to a casein solution in 3 per cent sodium hydroxide and the precipitate of copper hydroxide thus formed is filtered off a solution of the well known violet colour results the intensity of colour being proportional to the concentration of protein and thus obeying the Beer Lambert law It has further been found that the intensity of colour of the protein solution used is completely independent of the nature of the protein provided that the concentration of the protein solution is always the same hence the intensity does not depend on the kind of amino acids of which the proteins are built up The amount of copper contained in the samples calculated for an equal quantity of protein is the same throughout

The intensity of colour is also unaffected by the disintegration of the protein to peptone during the digestion of fibrin by pepsin during this process the intensity of the colour produced in the biuret reaction remains completely unchanged after five or six days

It is of further interest that the violet tint of the biuret reaction is not a single colour but consists of *two components* one red and one blue The extinction coefficients observed with the aid of the Pulfrich Stufenphotometer and plotted as a graph against the number of drops of copper sulphate solution added do not result in parallel straight lines for the red and the blue colour but in straight lines meeting at an angle The red component like the full colour is of equal intensity for different proteins in solutions of equal concentration The mutual independence of the colour components is also shown by the fact that when a violet colour test is diluted with the protein solution used the colour is shifted towards red the copper atoms obviously taking the place in the protein chains necessary for the formation of the red component the violet coloration on the contrary remains completely unchanged when the solutions are diluted with 3 per cent sodium hydroxide In no case is the variation of the colour above mentioned due to different valence of the red and blue copper When acidified both colours completely disappear but can be produced again by renewed alkalization if ammonia is used for this purpose instead of sodium hydroxide the well known deep blue complex colour is produced which can be used for the colorimetric determination of the bound copper By gradual addition of copper sulphate the red component alone is obtained the blue not appearing until a given number of drops of the reagent is reached

The Italian chemist Hugo Schiff who was one of the first to study the biuret reaction (also for proteins) states that nickel as well as copper with protein in an alkaline medium shows a characteristic golden yellow tint It was therefore of interest to investigate first the *nickel* and afterwards the *cobalt* compounds of proteins The colour of the latter samples is reddish brown Here the *quantitative relations* in comparison to those of the copper samples are noteworthy

According to our experiments 0 5 gm of casein combines with 56 7 mgm copper the full violet colour consisting of both the red and blue components correspondingly 26 1 mgm nickel and 17 4 mgm cobalt respectively are bound under analogous experimental conditions Taking the atomic weights of these three metals into consideration it may be seen that two atoms of copper correspond to one atom of nickel and three atoms of copper to one atom of cobalt These simple proportions are easily demonstrated by adding two of the above mentioned metals *one after the other* to the *same* protein test solution In this case the order in which the addition is made is of importance when nickel or cobalt is added to a copper sample one atom of the added nickel displaces two atoms of copper and one atom of cobalt three of them so that it becomes evident that nickel requires twice and cobalt three times the space taken by copper If however the test solution contains nickel or cobalt from the first and copper is then added no displacement at all takes place copper occupying the places still left free by nickel or cobalt that is one atom of copper is added to every atom of nickel and two atoms of copper to each atom of cobalt finally as many places are occupied in the protein chains as in the tests with copper alone

Conditions become more complicated when the investigation is extended to the *silver protein compounds* in alkaline medium, for here there is a tendency to keep larger quantities of the metal—evidently in a colloidal form—in solution Investigations appropriately applied, however, make it possible to reduce the quantity of silver present in the solution after filtration of the silver oxide to about 100 mgm per 0 5 gm casein, while the quantity of silver equivalent to 56 7 mgm copper amounts to 97 mgm So we have here one atom of silver for each atom of copper in the protein solution

With *gold* the conditions are strikingly similar to those with cobalt The quantity bound by 0 5 gm casein amounts to 58 5 mgm gold, this means, taking the atomic weights into consideration, that three atoms of copper correspond to one atom of gold If copper is afterwards added to a sample with gold, the gold (as was the case with nickel and cobalt) becomes concentrated into a smaller space, but is not displaced and two atoms of copper are added again to each atom of gold Yet other similarities between gold and cobalt are that the test solutions in both cases must stand for several days to give the above mentioned constant values, and furthermore that both these metal solutions are resistant to addition of acid thus differing from copper (see above) and nickel solutions, which are thereby caused to disintegrate at once

Different from the group copper, silver, gold, nickel and cobalt, all of which produce protein compounds in an alkaline medium, is another and larger group the members of which give no protein compounds *under our experimental conditions* To this group belong, among other metals, iron, manganese, zinc, mercury, etc We shall, however, not linger over this group

A few words may be added on the *point of linkage* of metals belonging to the first group Most probably this occurs at the nitrogen atoms of the peptide linkages This supposition is based, among other reasons, upon the results of methylation, for the number of methyl groups combined with nitrogen is *reduced* by the presence of the metal in copper nickel and cobalt protein solutions, in each case by about one third

New experiments by Dr Jesserer show that the precipitation of proteins with copper, etc, in *neutral* or *acid medium* takes place in the same way and that as much fresh copper is bound if the alkaline metal compound described above has already been produced, as in cases of native protein solutions The copper, etc, added in *acid* medium must therefore be located at a *different* place from the metal in alkaline conditions, and as, very probably, only the carboxyl groups can be regarded as the place of location for the copper in the former conditions, the only place left for the metal in the latter conditions is the *imino* and *amino* groups

A number of questions, significant both chemically and therapeutically, which have only been hinted at here, arise from the investigation of metallic protein compounds, which can easily be obtained in a dried state and are soluble in water The investigations, which I still hope to carry on, must be continued in diverse directions, among others, the catalytic powers of these substances must be examined

The Prosobranchs of Lake Tanganyika

By Prof. C. M. Yonge

WHEN Sir Richard Burton discovered Lake Tanganyika in 1858 his companion, Speke collected a number of shells from the shores These proved to be Prosobranchs of types hitherto unknown in fresh water Later investigations, notably those of the three Tanganyika expeditions, the first two under the leadership of J E S Moore[1] and the third under that of W A Cunnington[2], revealed in fuller detail the remarkable nature of the fauna with its great number of endemic species of fish, Crustacea, sponges and, above all, prosobranch Gastropoda Cunnington lists 84 species of Gastropoda of which 76 are endemic The majority, 72 species, are Prosobranchia and of these 68 are endemic Moreover 58 species have a heavy, frequently ornamented, shell, in appearance much more like marine than freshwater species Moore, elaborating a suggestion made originally by Gunther[3], regarded these, and the other endemic species, as a relict fauna, the descendants of a diverse collection of marine species which lived in this region when Tanganyika was, as he maintained, an arm of the Indian Ocean He described them as "halolimnic" species

In his book, "The Tanganyika Problem", Moore[1] claimed in support of his theory that the shells of these Prosobranchs were more closely allied to certain Jurassic fossils than to any modern species

Opposition was at once forthcoming from Smith[4] who showed that the resemblance to the Jurassic fossils was no more than superficial and from Pelseneer[5] who maintained that the majority of the halolimnic species could be included under the purely freshwater family Melaniidæ (subfamily Paramelaniinæ according to Thiele) Hudleston[6] a geologist specializing in Jurassic Mollusca was equally critical of Moore s conclusions

Cunnington who preferred Bourguignat s non committal term thalassoid for these species considered that they evolved during a period of isolation It is known that other deep isolated lakes notably Baikal possess many endemic species Fuchs[7] has recently suggested that prolonged aridity during the mid Pleistocene might by evaporation have caused a great increase in the salinity of the waters of Tanganyika and that this led to the appearance of the thalassoid species

The controversy which once raged over Moore s theories has long ago died down but it has unfortunately been succeeded by a complete neglect of the really significant side of his work his descriptions [8] and those of his pupil Miss Digby [9] of the anatomy of many of these thalassoid Prosobranchia From some original melaniid stock there have evolved a series of Prosobranchs adapted apparently for life in widely differing habitats within Tanganyika Some such as *Tiphobia horei Bathanalia howesi* and *Bythoceras iridescens* occur in deep water of more than a hundred fathoms and therefore presumably on a mud bottom others such as *Tanganyicia rufofilosa* and *Nassopsis nassa* on rocks in the region where the surf breaks *Spekia* and *Tanganyicia* are naticoid in appearance *Chytra* and *Limnotrochus* are trochoid *Paramelania* and *Nassopsis* less specialized in form and somewhat resembling *Nassa*

They must all of them be herbivorous This can now be deduced from the universal presence within them of a crystalline style lodged in a style sac which Moore described as an anterior chamber of the stomach Moore was struck by this common feature in their anatomy but regarded it as a primitive molluscan character and so as further evidence in support of his theory But it is now known that the crystalline style is a specialized structure occurring only in herbivorous Mollusca—namely in Lamellibranchia and in those herbivorous Gastropoda which feed by ciliary mechanisms or by the slow but almost continuous action of a radula [1] It occurs in all the diverse members of the Melaniidæ It is a noteworthy fact that although marine Gastropoda are most varied in feeding habit freshwater species are all herbivorous whether they possess styles as do the majority of freshwater Prosobranchia or not The most probable reason for the absence of carnivorous species is the specialized nature of the food in the majority of marine carnivores (this may certainly account for the absence of Opisthobranchs all of which herbivores as well as carnivores are highly specialized feeders) while scavenging species such as *Buccinum undatum* possibly failed to penetrate estuarine waters owing to the paucity there of dead animal material Moreover carnivorous Gastropoda in general are more specialized and so probably less adaptable

The freshwater Prosobranchs which have established themselves in freshwaters feed on algæ or decaying vegetation [1] Typically they occur among vegetation in shallow water as they do in the other African lakes such as Nyassa In Tanganyika it would appear that past conditions made possible considerable evolutionary change while the wide expanse and great depth of the lake nearly eight hundred fathoms provided a great variety of possible habitats But as revealed by the universal occurrence of a style the animals remained herbivorous It is therefore in the form of the radula that some indication may be obtained as to the mode of feeding The wide range in function of this organ—which in different species may serve for rasping seizing small particles or act purely as conveyor belt—has recently been emphasized by Peile [1] In *Nassopsis Spekia* and *Tanganyicia* it is composed of short stout teeth not unlike those of *Littorina* and probably rasps algæ off the rocks while in *Tiphobia* and *Bathanalia* it resembles more closely that of *Aporrhais* with long marginal teeth concerned probably with picking up detritus of vegetable origin on a mud bottom as I have shown for *Aporrhais* [4] Moore speaks of the resemblance of the radula of *Chytra* to that of *Capulus* and this is now known to act merely as a conveyor into the œsophagus of mucus laden masses collected by the enlarged ctenidium [1, 5] In certain species the great size of the gill indicates the possibility of ciliary feeding mechanisms which have certainly appeared independently of one another in a number of marine genera[15]

Thus from the consideration solely of anatomical detail it can be predicted that the Prosobranchia in Tanganyika are adapted for collecting vegetable matter in various forms living and dead and at various depths and on different bottoms A study of the living animals in relation to these habitats would certainly amplify this greatly Moore also indicates differences in the form of the osphradium which there is reason for regarding as an organ for estimating the amount of sediment that enters the mantle cavity[16] These differences in form may therefore be capable of correlation with the amount of sediment in the particular environment Finally, he showed that a number of species, *Tiphobia horei*, *Tanganyicia rufofilosa* and *Nassopsis nassa* are viviparous, the young being retained in a brood pouch The first of these lives in deep water, and viviparity may therefore be regarded as one of the adaptations which have made possible this unusual penetration into deep water by fresh water Prosobranchia but reasons for its occurrence in the other two, which are shore living species remain to be discovered

Viewed along these lines the Tanganyika problem assumes a different but no less fascinating form from that originally propounded by Moore Instead of regarding the endemic Prosobranchia as the descendants of a Jurassic marine fauna of diverse elements, we must consider them as springing in the main from a common origin and gradually becoming adapted for life in the variety of habitats which are present in the wide and deep waters of Lake Tanganyika As a result of adaptive processes, different species have assumed the shell form of many different types of marine species, while retaining in all cases the original specialization for a herbivorous diet as indicated by the presence of a crystalline style A full examination of these animals in their native surroundings, besides providing a fascinating study of adaptive radiation, might be expected to throw much light on the reasons for these convergences and so possibly, by inference, on the factors influencing the form of many marine species

Obituary Notices

Mr G N Huntly

GEORGE NEVILL HUNTLY, whose death at the age of seventy one years occurred on August 2, was educated at the Royal College of Science, where he took the associateship in chemistry and also obtained the London B Sc degree His earliest work was of a purely scientific character and dealt with the salts obtained by the action of nitric oxide on sulphites, a publication by Hantzsch anticipated his results, much to his disappointment

Huntly was for three and a half years demonstrator and assistant to Prof R V Tuson at the Royal Veterinary College Camden Town, and then demonstrator in chemistry in the State Medicine Laboratories at King's College London Afterwards he practised as a consultant, devoting himself especially to fuel work This led to a joint paper with J H Coste (*J Soc Chem Ind*, **32**, 62, 1913) on the estimation of water in commercial products Direct, gasometric and indirect methods, nine in all, were compared and special attention was paid to the indirect ones depending on loss of weight on drying In the case of coals it was found that the results were invariably higher when the coal was dried at a low pressure over sulphuric acid than when dried in the water oven, the importance of making such a direct comparison is evident Up to the date of his death, Huntly was serving on committees of the British Standards Institution (Fuel Testing) He also held several appointments as gas examiner under the Gas Undertakings Act.

With his extensive knowledge and experience, Huntly was a useful man in discussions, and he served on the Council of the Society of Public Analysts and Other Analytical Chemists, of which he was a vice president in 1919–20 He acted as an examiner to the Institute of Chemistry for two periods of several years, and served for two periods on the council of the Institute For very many years he contributed the weekly summary of the *Comptes rendus* of the Paris Academy of Sciences to NATURE To render into clear English even the titles of papers communicated to the Academy over the whole range of the physical and biological sciences is a very difficult task, yet Huntly accomplished it with remarkable success

Huntly married Hilda Wace in 1904, who survives him with a son and three daughters His friends deplore the loss of a man whose wide interests always made him a good companion

Miss Agnes T Neilson

THE untimely death of Miss A T Neilson on July 9 at the age of fifty eight years has deprived the Geological Department of the University of Glasgow of a brilliant and beloved teacher of twenty eight years' service Miss Neilson was educated at the Glasgow High School for Girls, Royal Technical College, West of Scotland Agricultural College, and the University of Glasgow She joined the staff of the Geological Department of the University in 1910, having previously worked in an unofficial capacity as curator in the Hunterian Museum She retained her interest in the last named institution until the end, and made many valuable additions to its mineral collections Miss Neilson specialized in the teaching of crystallography and mineralogy, and, in addition, was the chief organizer of the practical work of the Geological Department The latter was a difficult and trying task, especially during the period, round about 1930, in which the numbers of the Part 1 class rose to more than four hundred, but Miss Neilson discharged it in the most efficient and tactful manner and, in its performance, became guide, philosopher and friend to successive generations of students

Miss Neilson contributed a petrological chapter to the late Prof J W Gregory's "Geology and Rift Valleys of East Africa" (1921), and papers on the igneous rocks of Kenya and Somaliland to monographs of the Geological Department of the Hunterian Museum Her last piece of research work, in collaboration with the present writer, was on the remarkable igneous rocks of Mount Jombo, Kenya

Miss Neilson had an intellectual range far beyond the ordinary She was widely read, especially in philosophy and psychology, and could be regarded as an authority on psycho analysis She had a wonderful gift of condensing whole systems of philosophy into a few stanzas of concise and witty verse Her untoward loss is deeply felt by her colleagues in the Geological Department of the University of Glasgow, and by past and present students who enjoyed and appreciated her versatile ministrations G W T

We regret to announce the following deaths

Mr A Hutchinson, president in 1937 38 of the Iron and Steel Institute on August 20

Prof N Parravano, professor of inorganic chemistry in the University of Rome, secretary of the class of Physical, Mathematical and Natural Sciences of the Royal Academy of the Lincei, and one of the seventy academicians of the Pontifical Academy of Sciences, on August 10

News and Views

Centenary of Arthur Auwers, For.Mem.R.S.

On September 12 occurs the centenary of the birth of the distinguished German astronomer Georg Friedrich Julius Arthur Auwers, whose work led to the founding of the Bradley Medal of the Berlin Academy of Sciences and to whom British astronomers, to mark the fiftieth anniversary of his doctor's degree, presented a copy of Richardson's portrait of Bradley in the possession of the Royal Society This association of the name of Auwers with Bradley sprang from his life's work on the observation of stars and the formation of star catalogues Born at Göttingen, he passed through the University there and at twenty one years of age he became an assistant at Königsberg Observatory Three years later he was given a similar appointment at Gotha, and there made important observations on Procyon and Sirius Two years after the founding in 1865 of the *Astronomische Gesellschaft*, Argelander proposed the formation of a catalogue of all stars to the ninth magnitude from -2° to $+81^\circ$ Dec The catalogue was entrusted to Auwers, who had then become a member of the Berlin Academy of Sciences, of which he was afterwards secretary and president His great work was his "New Reduction of Bradley's Observations 1750–62", which occupied him from 1866 until 1876 He was besides concerned in the organization of the German Transit of Venus expeditions of 1874 and 1882 and drew up the reports of them He participated in Gill's determination of the solar parallax from the minor planets Victoria, Iris and Sappho, and in 1889 visited the Cape Observatory Auwers was the recipient of many honours, including the Gold Medal of the Royal Astronomical Society, and he was made a foreign member of the Royal Society He died on January 24, 1915, the first anniversary of the death of his constant friend Sir David Gill

Natives of Northern Rhodesia

In further reference to the native question in Northern Rhodesia discussed in another column of this issue of Nature (see p 449) attention may be directed to a statement of the problem, which appears in *Man* of August, by Mr W Godfrey Wilson, director of the recently founded Rhodes Livingstone Institute of Central African Studies The main function of the Institute is research into problems of culture contact Mr Wilson points out that, of the able bodied male population of the Territory, 44 per cent are *always at any one time in* European employment, while in the three 'denuded" provinces (out of the total of five provinces) this figure rises to 60 per cent, mostly employed outside the provincial boundaries The remoter districts "possess no agricultural product which can support the expense of 400 miles of road transport", and there is no alternative as a source of money to the sale of labour power There are thus, it is stated, three interrelated problems to be studied (1) What is happening in the new African society that consists of permanent and semi permanent residents in urban and industrial areas ? (2) What is happening among the group of men that alternate regularly between the urban and rural areas ? (3) What is happening to African society in the rural, and especially the "denuded areas" ? Mr. Wilson notes that the Government is seeking continuously to develop economic crops and products in the denuded areas which will provide an alternative to this high percentage of absentees from home, but hitherto without success. Pending the expert investigation of the Institute any suggestion as to a possible solution may seem premature; but it is evident that the situation is one of urgency.

Metallurgy and Prehistory

ONE of the more useful, if less obtrusive functions of the British Association has been the assistance given by modest subsidies in initiating lines of research, which could offer little to attract support from the sources commonly available. Not infrequently the result has been out of proportion to this modest beginning. What would appear likely to become an instance in point is the research committee on Sumerian copper from which a report was presented at the Cambridge meeting. This committee was first appointed some years ago for the purpose of investigating by comparative analysis the provenance of the copper in objects found by archæological excavation on Sumerian sites—a question of no little moment in determining the cultural contacts of the early peoples of Mesopotamia. Since then samples of early copper and bronze from a large number of sites have been examined, and a quantity of valuable data has been collected in the investigations which have been carried out under the direction of Dr. C. H. Desch, who has acted as secretary of the committee since its inception. Archæologists now recognize the advantage of the facilities for such an examination of their material by a committee which has at its disposal a technique developed by experience and a staff now familiar with the analysis of such metals and with the characteristics of ores from various regions mined in antiquity. In the period under review in the current report, for example, it is stated that analyses were made of prehistoric copper from Anatolia and India, of slags from Persia, of bronzes from central Asia and Brittany, of bronze and copper objects from Troy IX, and of electrum from Tell Ajjul in Palestine, while Sir Robert Mond's excavations in Guernsey have led to the microscopic investigation of early iron, and much information has, in consequence, been collected about the structure of bloomery iron. This work has been carried out at the National Physical Laboratory; but the readiness of archæologists to seek the assistance of the committee has led to the suggestion that it should be placed upon a more permanent basis and given a more general title.

Meare Lake Village, Somerset

WORK has been resumed at the Meare Lake Village, Somerset, for the season of 1938 under the direction of Dr. Arthur Bulleid and Mr. H. St. George Gray, and will continue until September 17. Operations this year are being concentrated on the middle area of the eastern half of the village, and at the moment, it is reported in *The Times* of September 2, the dwelling known as No. XXIV is under examination. In the southern section of this dwelling three floors can be seen. Two hearths have been uncovered, while near by there is a third, which belongs to the lowest floor. A number of lias stones have been found lying about this hearth. One of those is in an upright position. It is conjectured that it may have been the back of a seat set around the fire. On the east side of this hearth parallel timbers of oak lie on the surface of the peat. The small finds indicate that the inhabitants of the dwelling followed the occupation of weavers. Sawn and cut lengths of red deer antler and several pieces of iron are included among the finds, as well as the rim of a bowl in bronze. Personal ornaments are represented by a spiral finger ring of bronze and an amber bead inlaid with a spiral ornament in fused white material. Funds for the continuation of the excavations are urgently needed. It is much to be desired that the investigation of this important Iron Age site should be in no way hampered or delayed by lack of funds, for the results of investigations of the western half of the village have been prepared for publication and will be issued shortly. Their value will be impaired if investigation of the village as a whole falls short of completeness. Subscriptions may be sent to Mr. H. St. George Gray, The Castle, Taunton.

Hittites in Syria

SIR LEONARD WOOLLEY'S investigations at Atchana in the Amk Plain of Syria near Antioch have continued to extend the evidence of Hittite occupation. There is now a strong presumption that it may be assigned to so early a period as the first centuries of the second millennium B.C. An unanticipated discovery of a palace extension to the north has led to the uncovering not only of an earlier palace structure of a different orientation, dated tentatively at 1600 B.C., but also of two preceding city walls, and beneath these of the well preserved remains of an acropolis gateway of the eighteenth, or even the nineteenth, century B.C. According to a description of this work in Sir Leonard's report (*The Times*, Sept. 3) it is an imposing structure, roughly seventy five feet square, and consisting of twin towers joined by a bridge roofing the entrance passage. This passage has a system of three doorways. The gateway is built of mud brick reinforced by timbers with massive limestone faced piers for door jambs. It is the prototype of the gates of later Hittite cities, such as Carchemish and Boghaz Keui. Assuming that confirmatory evidence of origin is forthcoming, it is the oldest example of Hittite architecture yet known. The conclusion as to its age and the relation of the succession of remains on the north side are corroborated by evidence from the south side, which includes painted pottery and figurines going back to the first century of the second millennium. Even more interesting, if possible, is the occurrence here of Cypriote pottery, including a sherd dated at three centuries earlier than this type appears in Cyprus itself. This with other evidence, Sir Leonard suggests, appears to demand older mainland archetypes for the wares of Bronze Age Cyprus, and once more illustrates the inter relations of East and West in the early history of civilization.

A Cyclotron at the Science Museum

Prof E O Lawrence, of the University of California, has very kindly lent to the Science Museum the cyclotron, built by himself and Livingston in 1931, with which his first nuclear transmutation work was carried out in 1932 With an applied oscillating potential of only 4 000 volts peak this instrument was capable of accelerating protons to a speed equal to that produced by a fall through 1 200 000 volts The instrument was slightly modified afterwards by M G White for experiments on the scattering of protons in hydrogen and in this modified form it has now been placed on exhibition in the Science Museum in close proximity to Cockcroft and Walton s original apparatus, which accelerated protons through 600 700 kilovolts by means of a D C voltage of this amount derived from a transformer through a special voltage multiplying rectifier circuit Prof Lawrence has also lent to the Museum a small collection of photographs illustrating the development of the cyclotron One of these shows the two preliminary cyclotron models built by Lawrence and Edlefsen in 1930 which, though relatively crude gave encouragement for further development because they showed resonance effects, a further photograph shows the original cyclotron of Lawrence and Livingston which accelerated hydrogen molecular ions through 80 000 volts with an applied high frequency potential of less than 2 000 volts, and a series of views illustrates the latest cyclotron of Lawrence and Cooksey, which delivers currents of the order of 100 micro amperes of deuterons with energies in the neighbourhood of 8 million volts or a beam of alpha particles of about one micro ampere at 16 million volts

Waterspouts off the British Isles

Waterspouts are not such rare phenomena in the seas around the British Isles as is sometimes supposed Many of those that have been observed from coast stations of the Meteorological Office far out at sea at times when few people are in the neighbourhood have doubtless been recorded only at the Meteorological Office This applies especially to those seen in waters off the main shipping routes With the rapid increase of continental air services and the R A F expansion, opportunities of observation have multiplied, and statisticians of the future may have to be on their guard against accepting as real any sudden apparent increase of waterspout activity that may be shown during the re armament period Apart from this, there has been the slower growth of seaside population in the last thirty or forty years The four waterspouts seen off the sea front at Bexhill on September 1 would almost certainly have been unrecorded had they occurred before that period, although some farm labourer might have returned to his native village after his day s work in the fields overlooking the sea to recount over his pint of beer how he had seen the Devil in the form of a four trunked elephant leaning out of a thundercloud to drink out of the sea and how the Foul Fiend s breath had hung like a cloud over the surface of the sea as he drank Those readers who wish to know more about the phenomenon can consult a work by Alfred Wegener called Wind und Wasserhosen in Europa (Braunschweig, 1917) or an account of a discussion by the late M A Giblett of a paper by the same author in the official *Meteorological Magazine* for April 1929 The waterspout is a well known manifestation of the tornado, and is replaced by a dust devil if the tornado passes from the water to a dusty land surface

Institute of Brewing Researches

Sir Gilbert Morgan director of chemical research in the Department of Scientific and Industrial Research has been appointed chairman of the Research Fund Committee of the Institute of Brewing For many years the Institute has been carrying out researches covering a wide range chiefly in connexion with the raw materials of brewing, namely barley hops and yeast which have been carried out in collaboration with numerous experts and with the following institutions namely East Malling Research Station (East Malling) Imperial Council for Agricultural Research (India) Municipal College of Technology (Manchester) National Institute of Agricultural Botany (Cambridge) Rothamsted Experimental Station (Harpenden) South Eastern Agricultural College (Wye) and in the University of Birmingham The offices of the Institute are at Brewers Hall Addle Street London E C 2 It will be recalled that Sir Gilbert s impending retirement from his post under the Department of Scientific and Industrial Research was recently announced (see NATURE July 30 p 200)

Power Supply in Small-Scale Industries

The Vienna Sectional Meeting of the World Power Conference which was concluded on September 2, was most successful Of the thirteen British papers presented four are concerned with power supply to small scale industries An important paper on this subject was presented by J N Waite, electrical engineer of Hull and F H Clough of the British Thomson Houston Co Ltd They point out that the market depends on the particular district served If the local supply undertaking finds it economic to encourage such uses as cooking water heating and space heating then the demand for power will probably be large They estimate that the total market for the uses covered in their paper is of the order of 11 thousand million units per annum Distribution methods are becoming standardized and new uses for electrical energy are steadily arising Attention is directed to the change in the economic position that may follow active development of what are now normally off peak demands provided new peak demands are created The authors emphasize the value of flexible tariffs as these promote uses which create 'diversity in demand Judicious expenditure on canvassing is considered wise The paper concludes with observations on the influence of taxation upon tariffs A paper by Mr W Dieterichs, of the Gas Light and Coke Company, deals with Gas for Small Scale Industries ' He stated that the gas industry has developed from a manufacturer and seller of a commodity into a specialized heat service

The organization being developed by the British gas industry in order to provide such a service is described. It is emphasized that while large firms can burn coal efficiently themselves or use it in producers, and can employ technologists of their own, small firms must depend entirely on outside specialized services. Hence although large firms use more gas, the supplying of small firms is of particular value to the gas industry.

Energy Supply for Electric Railways

ANOTHER paper read at the Vienna Sectional Meeting of the World Power Conference, by Mr. F. Lydall, a member of the well known firm of Merz and McLellan, consulting engineers, discusses the requirements and the supply of energy for electric railways. It is divided into four sections. The first discusses the energy requirements for electric traction. Mr. Lydall shows that these are much smaller than usually estimated. As an approximation he gives 50 kilowatt hours per 1000 ton miles. In the winter months about ten per cent has to be added to this for train heating. The second part deals with the consumption of energy for railway traction in Great Britain, giving figures for each electrified line, with the source of supply and the half hourly maximum demand. In the third part fluctuations of traction load and the ratio of the average to the maximum demand are discussed. Mr. Lydall states that, in general, for a new scheme of electrification, it would not pay a railway to provide its own power. The Southern Railway derives its electricity from three sources, its own power station, a power company and the Central Electricity Board. On the subject of the supply of energy for electric railways, fifteen papers were received by the Conference—four from France, two each from Germany and Switzerland, and one each from the Argentine, Denmark, Japan, Norway, Sweden, Great Britain and the United States.

The Central. Armstrong Memorial Number

OLD Centralians, their children and their wives, their servants and even the stranger within their gates, will do well to read the Armstrong Memorial Number of *The Central* (35, No. 83, June 1938) to be reminded in simple, vigorous form of the life work of a rugged old man whom so many of us were proud to call friend. The photographs of him are excellent and the appreciations of one whose giant mental stature made any attempt at appraising his qualities during his lifetime a graceless task—was he not "H. E. A."?—are just. Dr. E. F. Armstrong is to be congratulated on his choice of material no less than upon his handling of his father's documents. The result is worthy of the considerable labour that must have gone to the making, and it has the authentic Armstrong ring. The number must have pleased the professor himself—had one been able to take it round to show him. The author's lively wit illumines the section of his autobiography included here. Chemistry was to "H. E. A." a philosophy of life, and he had a biting scorn for those who thought it merely a means of earning a livelihood. He could never recommend us to suffer fools gladly, and he had an eagle eye for folly in scientific research. His (to his friends) familiar advice. "Sack the lot!" was more indicative of his true insight into the problems of this generation than many supposed. One is glad to think that this almost classic phrase has found a place in his memorial number of *The Central*: the old man would have had it so!

Centenary of Portuguese Medical Schools

PHILATELISTS and medical historians among others will be interested to know of the recent issue of a stamp of 25 centavos, of which a correspondent has sent us a specimen, on the occasion of the celebration on March 6, 1937, of the foundation of the medical schools of Lisbon and Oporto. Before the establishment of these schools, as we learn from a contemporary account (*British and Foreign Medical Review*, p. 284, July 1838), the majority of medical men in Portugal were very ignorant, knowing little of either anatomy or surgery. Many surgeons indeed were in practice who had never studied at any school. These men had not been examined by professors or teachers, but merely by surgeons in any part of the country selected by the chief surgeon of the kingdom. In some cases, no authority of any kind had been given. The value of the medical instruction in the new schools was shown not only by the presence of the most eminent Portuguese physicians and surgeons on the staff but also by the fact that shortly after the foundation of these schools the departure of future doctors for qualification abroad came to an end. Moreover, the improvement in education and the high standard required of candidates before receiving their diploma resulted in a considerable rise in the social status of the medical profession in Portugal.

Bio-Morphosis

THE first number of a new journal, *Bio Morphosis—International Journal of Morphology and Biology of Man and the higher Vertebrates*, has recently appeared. Prof. Bluntschli, of Bern, is principal editor, and the publisher is Karger, of Basle and Leipzig. The editorial board includes representatives from Sweden, Poland, China, Hungary, Holland, the United States, etc., and such well known names as those of Profs. J. P. Hill, G. Levi and E. Fauré Fremiet. In his general introduction, the editor points out that morphological and physiological researches have for decades been isolated from one another. The journal therefore has the very laudable aim of reconciling and exchanging the ideas of these two ways of biological investigation. Contributions on subjects possessing both morphological and physiological interest are therefore invited. They may be in English or French or German, summaries in the languages not used being provided at the conclusion of the paper. In the first issue, F. Weidenreich discusses the evolution of man in the light of new discoveries about *Sinanthropus*, *Pithecanthropus*, etc., coming to the rather surprising conclusion that "the developmental factors of Lamarckian and Darwinian conception are of no importance, the essence of the evolution being an independent progressive differentia

Announcing the

ANNUAL REVIEW OF PHYSIOLOGY

Editorial Committee
A J Carlson
J F Fulton
M H Jacobs
F C Mann
W J Meek

Publication date, Volume I, March, 1939
Published by
AMERICAN PHYSIOLOGICAL SOCIETY
and
ANNUAL REVIEW OF BIOCHEMISTRY

Joint Board of Management
C D Leake
J Murray Luck
W J Meek
C L A Schmidt
Editor
J Murray Luck

The new Review, to appear annually, will consist of critical descriptions of the research done in the various fields of physiology during the previous year or biennium It will be similar in style and format to the Annual Review of Biochemistry

Contents, Volume I—Permeability—M H Jacobs, Bioelectric Phenomena—D W Bronk; Physiological Effects of Radiant Energy—Janet H Clark, Physiological Aspects of Genetics—G. W Beadle, Developmental Physiology—Joseph Needham, Growth—C B Davenport, Temperature Regulation—A C Burton, Energy Metabolism—J R Murlin, Respiratory System—R Gesell, Muscle—E Bozler, Digestive System—A C Ivy, Liver and Bile—F C Mann, Blood—J H Austin, Peripheral Circulation—H C Bazett, Heart—J A E Eyster, Brain Potentials—H Davis, Spinal Cord and Reflexes—J C Eccles, Physiological Psychology—C P Stone and E R Hilgard, Sense Organs—J M D. Olmsted, Autonomic Nervous System—J Hinsey, Endocrine System—H M Evans, Kidney—Homer Smith, Reproductive System—E T Engle, General and Local Anæsthetics—M H Seevers, Applied Physiology—D B. Dill

HYPNOSIS:
its Meaning and Practice

ERIC CUDDON

"Mr. Cuddon is a practising hypnotist with a lively interest in the fringes bordering his subject. He describes not only the technique and limits of hypnotism as applied to human 'cases', but makes brief, suggestive excursions into the effect on animals, mass hypnotism and hypnotism at a distance. . . . This is the clearest and best book on a perplexing psychological subject which has come my way"
—*Time and Tide*

"The book can be recommended to all readers, lay and medical, to provide a practical conception of modern suggestion therapy."
—*The Medical Times.*

✱ *This is one of an important new series 'Psychical Experiences', 3s. 6d each net A list of volumes in the series will gladly be sent free on application to the publishers, MESSRS. BELL, 6 Portugal Street, London, W C.2.*

AN ORIENTATION IN SCIENCE

By Eleven Members of the University of Rochester Faculty

C. W. WATKEYS, Editor

560 pages, 9 × 6, 281 illustrations, 21/- net

A COMPREHENSIVE survey of natural science as developed during the past ten years at the University of Rochester. As one reader of the book put it : "Science is transformed in this book from a mysterious matter into an understandable, enjoyable and useful field of knowledge that is indispensable to an understanding of the modern world"

The book is unique in that it successfully covers the essentials of many different fields. Of particular significance is the discussion of the relationship of physics and chemistry, geology and biology, physiology and psychology, chemistry and biology, and every other possible combination of the fields listed in the table of contents below.

In all these fields the contributions of mathematics are carefully considered

tion of the type itself" A Weber has a short paper on the nerve fibres of the chick after spinal cord injuries to the embryo , and the geometrical characteristics of the head flexures, etc of the chick embryo are described by E Bujard A very interesting paper is that by A Portmann, who discusses the evolution of the mammalian placenta, concluding that although the histological classification of Grosser has much physiological importance, it cannot serve as the basis for an evolutionary scheme A new scheme is provided There is also an interesting schematization of the formation of the amnion in Eutheria by R A Goetz, who describes his work on the early development of the Tenrecoidea

Towns and Industry

ONE of the great merits of the broadsheets issued by P E P (Political and Economic Planning) is the way in which they direct attention to neglected problems or to changing conditions which are creating new problems A recent broadsheet on towns and industry is intended to stimulate discussion regarding the town as a background of industry, and as a social organism the development of which can be and is being shaped Its analysis of the different types of town from the village and country town, through the traffic town, the port, the mining camp town, such as Corby, Kinlochleven and Fort William, the military town, the cathedral city, the school and university town, the resort the residential town the dormitory town the planned town to the metropolitan centres, and particularly its bearing on transport questions indicates very clearly how imperative is decision whether to accept the types of town resulting from the blind play of economic and social decisions, all taken regardless of the type of town they will develop, or whether to examine the different possible types of town, to agree on the merits and demerits of each, and to make economic and social decisions within a framework which will ensure that the towns of the future combine the maximum advantages and the minimum drawbacks of their various types In the words of the broadsheet, our towns are, with few exceptions, deformed and diseased organisms It is clear that no less than in the sphere of physical fitness, the conquest and eradication of disease depend on dispassionate scientific investigation

Technical Information and Research

A PAPER by Dr E S Hedges and Dr C E Homer on "The Role of Technical Information in Industrial Research and Development", presented at the World Congress on Universal Documentation in Paris last year, has been included as No 6 in the Miscellaneous Publications of the International Tin Research and Development Council The paper reviews the functions of an information department in industrial research and development and describes the methods of disseminating technical information with particular reference to those used for the collection, storing and distribution of information by the International Tin Research and Development Council The policy of the Council of making available to those interested all information obtained is carried out to some extent by replies to inquiries but more generally by publishing all suitable information in the Technical Papers or Bulletins of the Council The first are issued in several series Series A is devoted to accounts of original work carried out by the Council's investigators and usually consists of reprints of papers presented to scientific societies , Series B consists of comprehensive accounts of special subjects , Series C is reserved for reports of new applications of tin , and Series D contains reports of original research by other organizations The Miscellaneous Publications deal with general nontechnical topics of interest to the tin industry while the Bulletins, which are written in a less severely technical style endeavour to provide a survey of the tin consuming industries

Study of Hormones

WE have received A Symposium on Hormones , being the Sigma Xi Lectures for 1936 37 in the Ohio State University (*Ohio J Sci* , 37 No 6 315–463 , 1937) These lectures are delivered biennially and the present volume is the third of the series Owing to the size of the field, only certain aspects of each subject have been selected by the different authors for elucidation and no discussion of the hormones of the parathyroids thymus or pineal gland has been possible The lectures include, however, two devoted to the growing field of the plant hormones, as well as discussions on the relationship of internal secretion to the nervous system by Leon Asher, and the less well known hormones of the gastro intestinal tract by A C Ivy C H Best gives an interesting account of the prolongation of the action of insulin by addition of protamine and zinc The sex hormones are dealt with by W O Nelson and H O Haterius, the thyroid hormone by D Marine the hormones of the adrenal gland by F A Hartman and those of the anterior lobe of the pituitary gland by O Riddle In each case the author has himself done much by experiment to advance our knowledge of the subject with which he deals

Raising the Compulsory School Attendance Age

LOCAL EDUCATION AUTHORITIES were advised by the Board of Education s circular 1457 as to preparations for meeting the situations arising when under the Education Act of 1936 applications are made for exemption from the obligation to continue attendance at school after the age of fourteen years The preparations recommended comprise a survey with the help of juvenile employment committees and inspectors of factories, of the conditions and circumstances in which children generally between fourteen and fifteen years of age are at present employed the prescription of forms for application for exemption, school reports and medical reports , the adoption of procedures already tested and found useful in regard to vocational advice , and co operation between authorities for contiguous areas The National Union of Teachers has issued a sixteen page pamphlet commenting on the circular and making a number of other suggestions and re affirming the Union s opinion that there should be no exemptions

Vaccination and Smallpox

IN the recent issue of *The Fight against Disease* (26, No 1, 1938), the quarterly journal of the Research Defence Society, Dr Monckton Copeman reviews the evidence of the value of vaccination as a preventive of smallpox A striking instance is that of Soviet Russia where vaccination was not made compulsory until 1918 In 1915, there were 126 518 cases of smallpox in 1925, 18,514, and in 1929 only 6 406 cases In the subsequent quinquennium, there was an increase in the incidence of the disease owing to laxity in carrying out vaccination, but more rigorous measures being adopted, the number of smallpox cases fell from 17 327 in 1934 to 3,156 in 1935, and to 385 in 1936, while in the first quarter of 1937 not a single case was notified

The Treatment of Malaria

THE Malaria Commission of the Health Organisation of the League of Nations has published its fourth report a valuable and important document, dealing with the treatment, and to a less extent with the prevention of malaria (League of Nations Bulletin of the Health Organisation, No 6 London Allen and Unwin, 1937 2*s* 6*d*) The Malaria Commission has been working for the last three years in making as exact a comparison as possible of the efficacy of quinine and the two synthetic drugs atebrin and plasmoquine for treatment of patients, for clinical prophylaxis, and for mass treatment and attempts at eradication of malaria In treatment of an attack, quinine in daily doses of 1 0–1 3 gm , and atebrin in daily doses of 0 3 gm , are almost equally efficient in causing disappearance of the trophozoites of the three forms of fever—quartan, benign tertian and malignant tertian —atebrin having a somewhat more rapid action than quinine Both these drugs also act upon the gametocytes of the quartan and benign tertian parasites, but have little or no action on those of the malignant tertian parasite Plasmoquine is active upon the trophozoites of the quartan parasite, is less active upon the benign tertian, and is without action upon the malignant tertian On the other hand, this drug is active upon the gametocytes of all three parasites, but particularly upon those of the malignant tertian parasite The association of quinine with plasmoquine represents one of the most efficacious methods of treating malaria It is interesting to note that quinine thus still maintains its place as one of the most efficient drugs in the treatment of malaria, and it has the advantage that with the usual doses it has little depressive or toxic effect, and is the safest drug to use without constant medical supervision

Earthquake in the Philippines

ON Monday, August 29, during the night, an earthquake occurred in the Philippine Islands (*The Times*, Aug 31) The epicentre was to the south east of Manila between the islands of Masbate and Samar, since both these islands were affected, property being destroyed and several people being injured No large earthquake has occurred in the Philippines since Batangas was destroyed just before 11 p m on the night of December 14, 1901, though small earthquakes are common in that part of the world The epicentre of the present shock is somewhat to the west of the most important seismic zone south of Manila This latter is the ocean trough known as the Philippine Deep lying to the east of Mindanao No fewer than 102 epicentres between 1920 and 1929 determined by Father W G Repetti, S J , of the Manila Observatory, were found to lie chiefly in two areas concentrated on lat 6° 30′ N , long 126° 40′ E , and lat 7° 45 N , long 127° 10 E

The Los Angeles Earthquake

A STRONG earthquake is reported as having taken place on Tuesday night, August 30, in the neighbourhood of Los Angeles, but little damage is mentioned A previous earthquake in Los Angeles occurred on January 28, 1931, at $12^h\ 50^m$ P S T , having its epicentre near the intersection of 48th Street and 2nd Avenue, Los Angeles (34 00′ N , 180° 19′ W), with intensity 4 on the Rossi Forel scale, and affecting an area of about one and a half kilometres radius The shock was studied by C F Richter of Pasadena, who stated that the epicentre was on the prolongation of the abrupt north face of the Baldwin Hills, previously considered an erosion feature, but now suspected to be a fault The present earthquake bears many resemblances to its predecessor, and we await further details with interest

North of England Zoological Society

THE North of England Zoological Society, which owns and controls the Chester Zoological Gardens, is making an appeal to raise funds to place the Society in a stronger financial position The objects of the Society are to establish a public zoological garden for the purpose of keeping wild animals and birds in spacious enclosures so that they can be admired and studied in safety The Society is bound by its memorandum of association to use all its income for the promotion of its objects, it is not allowed to have a share capital, hence the necessity for raising a fund for this purpose Further information can be obtained from the Secretary, North of England Zoological Society, Zoological Gardens, Upton-upon-Chester

Effect of Floods in East Norfolk

MR E V NEWNHAM, referring to his letter in NATURE of August 6, states that the date of the severe gale mentioned by him should have been June 29, that is to say, it came nearly at spring-tide Further, in line 3 of the penultimate paragraph of the letter, sledge covered' shallows should be read 'sedge covered' shallows Mr Newnham continues "I have not yet studied in detail the official statistics relating to the general character of the weather in the autumn and winter following a spring drought like that of 1938, but Dr C E P Brooks of the Meteorological Office is of the opinion that the statistics will show that more than the average degree of storminess over England is usual It is to be hoped that those gales that blow from the north-west will not come at spring tides"

Aeronautical Development in Australia

IN pursuance of its policy of encouraging aeronautical development in the Commonwealth, the Australian Government announced some time ago that it would assist in the initiation and maintenance of a chair of aeronautics at one of the universities The choice lay between Sydney and Melbourne, with much to be said in favour of each On the balance, it has been decided that Sydney is the more appropriate place, and steps will be taken at once to establish a school The Government will provide £32,000 for capital expenditure and £3,000 per annum for maintenance The Commonwealth Government has also decided to lend its support to the further development of meteorological science, being led to this largely by the requirements of aircraft services, both military and civil An associate professorship will be created in the University of Melbourne, the Government contributing £4,000 for expenditure on equipment and £1,500 per annum for maintenance

Engineering Public Relations

THE recently formed Engineering Public Relations Committee, supported by fourteen of the leading professional engineers' institutions, has arranged for the delivery of a series of twelve lectures at the Mary Ward Settlement, Tavistock Place, W C 1, on Tuesdays at 8 p m , commencing on September 27. The first lecture is to be given by Lieut -Colonel F H. Budden, public relations officer of the Committee, on "The Engineer and the Community" , subsequent lectures will be given by other eminent engineers on their special subjects, emphasizing how engineers have contributed to the welfare of the community in the past, how they are planning for present development, and what will be the effect of such development on society in the future Lectures 2–5 are specifically directed to the civil engineering of London, its roads, water-supply, buildings, and sanitation The remaining lectures deal with the implications of this machine age , the mass-production of goods, generation of power, production of wealth, transport by road, rail, and air, and the effect of these and mechanical forms of entertainment on economic life. A syllabus of the lectures and tickets for the series (3*s* 6*d*) can be obtained from the Mary Ward Settlement

Announcements

PROF. C O. E. BERGSTRAND, professor of astronomy in the University of Uppsala, has been elected *correspondant* for the Section of Astronomy of the Paris Academy of Sciences, in succession to Prof. L. Picart, professor of astronomy in the University of Bordeaux, who has been made a non-resident member of the Academy

DR H J. S SAND, head of the Department of Inorganic and Physical Chemistry at the Sir John Cass Technical Institute, London, E C 3, is retiring at Christmas. Dr. E de Barry Barnett, at present head of the Department of Organic and Applied Chemistry, has been appointed head of the combined chemistry departments as from January 1, 1939

ON the occasion of the centenary celebration of Dalhousie University, Halifax, Nova Scotia, the honorary degree of LL D will be bestowed on Lord Macmillan, Sir Walter Langdon-Brown and Prof Ernest Barker

THE Bavarian Academy of Sciences has presented the silver medal *Bene Merenti* to the pharmacologist Dr Ernst Frickhinger of Nordlingen

A DUTCH Congress of public health will be held at Maestricht on September 15–17 Further information can be obtained from Prof C T Van Oyen, Billstraat 166, Utrecht

THE twelfth Congress of Anæsthesia will be held in New York on October 16–20 Further information can be obtained from Dr F H McMechan, 318 Hotel Westlake, Rocking River, Ohio

THE 1938 39 session of the Royal Sanitary Institute courses of lectures will begin on Monday, September 19 The courses will be for sanitary inspectors, inspectors of meat and other foods, smoke inspectors, and will also deal with hygiene and sanitation in general and sanitary science applied to buildings and public works Further information can be obtained from the Secretary, 90 Buckingham Palace Road, S W 1

DR I. SNAPPER, professor of medicine in the University of Amsterdam and director of the clinic of internal medicine at the Wilhelmina Hospital, has been appointed professor of medicine at the Peiping Union Medical College

ACCORDING to the central office of statistics of Poland, there has been a recent decline in the birth-rate of that country During the first six months of 1937 the births numbered 433,306 compared with 454,437 in the corresponding period of 1936 During the same period of 1937 the number of deaths rose to 254,549 from 236,578 in the first half of 1936, so that the increases of population fell from 217,859 to 178,757 or from 12 9 to 10 5 per 1,000 inhabitants

A LEVERHULME research grant has been awarded to Dr G E Friend for an inquiry into gain and loss of weight of 5,000 boys in day and boarding schools as a possible manifestation of fatigue

THE Commission for the Special Areas has made a grant of £50,000 for the centenary appeal fund of the Cardiff Royal Infirmary for the purpose of reconstruction, on the condition that the infirmary shall join a regional scheme for the co-ordination of hospital facilities and services in the special area

ERRATUM In NATURE of August 13, p. 289, letter entitled "Radio Fadeouts, Auroras and Magnetic Storms", first paragraph, last line, for "January 20–22 and January 24–26, 1937" read "January 20–22 and January 24–26, 1938"

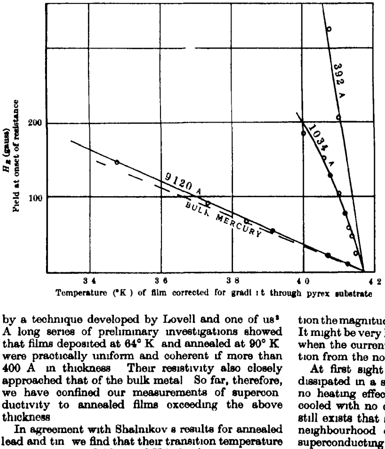
Superconductivity of Thin Films of Mercury

SHALNIKOV[1] in a recent letter has reported some results on the superconductivity of lead and tin films prepared by evaporative deposition We have recently obtained some measurements on the superconductivity of mercury films which were prepared by a technique developed by Lovell and one of us[2] A long series of preliminary investigations showed that films deposited at 64° K and annealed at 90° K were practically uniform and coherent if more than 400 A in thickness Their resistivity also closely approached that of the bulk metal So far, therefore, we have confined our measurements of superconductivity to annealed films exceeding the above thickness



In agreement with Shalnikov s results for annealed lead and tin we find that their transition temperature in zero magnetic field (4 14° K) closely approximates to that of the bulk metal (4 17° K) We attribute no significance to this small consistent difference of 0 03° K since the films are deposited on one side of a pyrex wall which is cooled on the other side by liquid helium, and temperatures are estimated from the vapour pressure of the helium bath A temperature difference of this order can easily arise from absorption of heat radiation on the outer face of the pyrex

We find, also in agreement with Shalnikov, that the films show very high magnetic threshold fields If the field is applied parallel to the plane of the film, complete restoration of resistance takes place over a considerable range of magnetic field, but the first onset of resistance is quite sharp

The accompanying figure illustrates the dependence of this onset' field upon temperature for three different films with thicknesses as shown The field changes by a factor of more than fifteen as we pass from the thinnest to the thickest film For comparison the critical field for bulk mercury is appended, it coincides satisfactorily with the critical field for the film 9 12 × 10^{-5} cm thick But it must be pointed out that even for this thick film considerably greater fields are needed to restore the resistance completely, whereas for the bulk metal the transition is sharp

Shalnikov gives details of the destruction of superconductivity by large currents We have not investigated the effect of high current density on the films because of the difficulty of correcting for the temperature gradient through the glass surface arising from the power dissipated in the film This may give rise to large temperature differences for example, assuming a current of 60 ma traverses a film 0 5 cm broad deposited on a pyrex surface 0 1 cm thick we find that a temperature difference could exist of nearly 0 9° C per ohm of a square patch (Thermal conductivity of pyrex extrapolated from Stephens' results[3]) Shalnikov does not mention the magnitude of the correction made for this effect It might be very large for the thinnest films, at any rate when the current is being reduced to give the transition from the normal to the superconducting state

At first sight it appears that since no power is dissipated in a superconducting film, there should be no heating effect at any currents when the film is cooled with no current flowing But the possibility still exists that some section of the film say, in the neighbourhood of the current leads may be non superconducting Heat will be developed here and will spread by conduction so that successive sections of the film show normal resistance, and the process will be cumulative Thus we feel that the interpretation of Shalnikov s results for the critical current should be accepted with some reserve

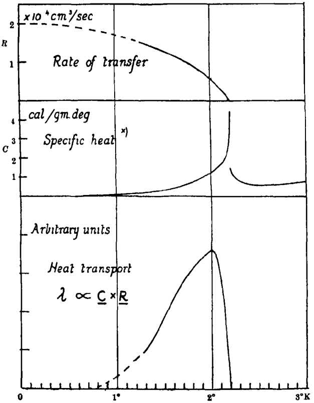
Transfer Effect in Liquid Helium II

WE have recently reported on observations of a 'transfer' of liquid helium II on glass[1] Since then a great number of various experiments on this effect have been carried out, and, as the observed phenomena seem not only of interest in respect to theory but also in their influence on experimental conditions[2], a short summary of the more important results follows

The rate of transfer depends only on temperature and is practically *independent* of the difference in height between two levels (except if the higher level is very near—1 5 cm or less—the top of the barrier) This shows that although such a difference in height gives rise to a transfer, the gravity is not the driving force We conclude, therefore, that the rate of transfer is a characteristic quantity which only depends on the thermal state of liquid helium II



×) Keesom and Keesom, *Physica* **2** 557 (1935)

Although a higher rate of transfer per unit surface was observed on drawn copper wires, the rate on polished copper was found to be exactly the same as on glass We attribute the high rate on drawn wires to the influence of surface inhomogeneities, and conclude that the rate of transfer is not influenced by the underlying material

The transfer between two levels is limited by the narrowest part of the connecting surface *above* the higher level. A constriction below the higher level does not restrict the flow, as at places below the higher level drops of free liquid can be formed

The thickness of the helium film in which the transfer takes place was determined directly by the amount of liquid deposited on a known surface It was found to be about 5×10^{-6} cm thick and seemed not to change in order of magnitude between 2·1° and 1 5° K Above the λ point it was not more than 10^{-7} cm thick

Experiments on the heat transport through the film showed that less than three per cent of the trans ported heat was due to 'conduction' in the film, and that the whole heat transport could be accounted for by the transfer effect, that is, by actual flow of helium along the surface in the direction towards higher temperature This means that the high amount which evaporates from vessels containing liquid helium II is not due to heat conducted through the film into the vessel as was suggested by Kikoin and Lasarew[3], but is due to helium being transferred along the walls of the connecting tube out of the vessel This explanation agrees well with an assumption of Rollin and Simon[4]

A discussion of these phenomena in respect to the various theories of the properties of helium II has to be left to a detailed report It is evident that our observation of an actual transport of mass in the film lends weight to the suggestion[5] that the high heat conductivity of the free liquid is also due to a similar process Such a heat transport would depend on the transported mass and on the specific heat Assuming that the amount transported in the free liquid is proportional to the rate of transfer observed in our experiments, we arrive for the heat transport as a function of temperature at a curve with a maximum at 2° K (see accompanying figure) It must be added that such a picture has, of course, to be considered as a first approximation only

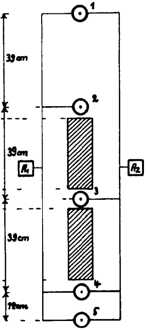
Search for Exchange Phenomena in Cosmic Rays

ACCORDING to the exchange theory[1,2], a collision between a sufficiently swift free proton (or neutron) and a nuclear neutron (or proton) may result in a reciprocal transformation of the colliding particles into each other A radiation consisting of protons of very high energy should therefore behave as if its particles alternately lost and recovered their ionizing faculty The mean distance separating such successive events, calculated on non relativistic theory, should be equal to about 2 cm in lead and should be some five times longer if relativity is taken into account

Jacobsen and, independently, Clay[3] have tried to discover an exchange effect of this type in the penetrating component of cosmic rays Double and triple coincidences were compared between counters (1, 2) and (1, 2, 3), all counters being disposed, with their axes parallel and horizontal, in a vertical plane and the pairs (1, 2) and (2, 3) being separated by 10 cm of lead If a proton goes into a neutron in the upper part and this neutron goes into a proton in the lower part, then there should be more coincidences (1, 2) than (1, 2, 3) After subtraction of accidental coincidences, however, the two series gave identical results

Although it is practically certain that the protons can constitute only a small fraction of the penetrating cosmic particles, we thought that the repetition of this experiment, in an improved form, may present some interest On one hand, it may lead to the appreciation of an upper limit of the relative number of protons in cosmic rays On the other hand, the properties of the heavy electron being very little known, one cannot exclude *a priori* the existence of an exchange effect exhibited by the new particles of the type described above



We have used five counters as shown in the accompanying figure, having an effective area of about 100 cm^2 The uppermost pair (1, 2) was separated by 35 cm air, the pairs (2 3) and (3 4) by 30 cm lead and 5 cm air and the pair (4 5) by 7 cm air The experiment consisted in comparing quadruple coincidences of the set (1 2, 4 5) with those of the set (1, 3, 4, 5) The first case corresponds to the case (1, 2) of Jacobsen s experiment and the second case to the arrangement (1, 2, 3) We have preferred to count in both cases coincidences of equal multiplicity, instead of comparing double to triple coincidences The pair (4, 5) has been added, in order to select only those particles travelling in a nearly vertical direction, because some previous experiments have shown that, owing to the scattering and showers taking place in lead, there may be particles coming obliquely through the counters 2 and 4, but not through the counter 3

In order to reduce statistical errors, the sets (1, 2, 4, 5) and (1, 3, 4, 5) were connected *simultaneously* to two separate amplifiers A_1 and A_2 and counting was made in alternating series in which the roles of A_1 and A_2 were interchanged The figures given below represent, for each set, the average value of the numbers of coincidences obtained with the two amplifiers (which were very nearly equal)

Set (1, 2, 4, 5) .	3 44 ± 0 2 hour
Set (1, 3, 4, 5)	3 53 ± 0 2 hour

We can conclude from this experiment that if the particles constituting the bulk of the penetrating component give rise to any exchange effect, the mean free path in lead for this effect is much longer than 30 cm On the other hand, taking into account the statistical error of the ratio of the two figures, which is certainly less, owing to the simultaneous counting, than the error of each series that is, than 5 7 per cent, and assuming the mean free length for the exchange proton neutron to be as large as 10 cm , we calculate that the relative number of protons present in cosmic penetrating radiation must be smaller than 0 2

The Adsorption of Deuterium on some Promoted Molybdenum Oxides

SOME very interesting results have been obtained during the course of an investigation into the adsorption of deuterium and hydrogen on surfaces of zinc nickel and cobalt molybdenum oxides

With all three adsorbents pronounced Van der Waals adsorption occurred at 77° K , deuterium being adsorbed to a greater extent than hydrogen These results are in accordance with the work of Taylor and Smith[1], who deduced a 2 9 per cent increase in the adsorption of deuterium over that of hydrogen on zinc oxide at 80° K Taylor explained this increase in adsorption by the greater ease of condensation of the deuterium

The low temperature heats of adsorption for deuterium on the three mixed oxides were found in every case to be some 600 cal lower than those for hydrogen These values were determined from the low temperature isotherms

Differences were also found between the adsorption of the two isotopes in the region of activated adsorption (184–444° C) At 218° C the rate of adsorption of deuterium was lower than that of hydrogen for all three adsorbents Before studying the adsorption of deuterium, it was proved essential first to flush out the adsorbent with deuterium at a high temperature (c 400° C) If this treatment was omitted, that is, if adsorption experiments with deuterium were carried out immediately after experiments with hydrogen, it was found that the measured adsorption of deuterium was the same as that of hydrogen The object of this preliminary treatment was the displacement of residual hydrogen from the surface, this hydrogen not being removable by evacuation It has been demonstrated that if this procedure is not undertaken, erroneous results are obtained due to the HD reaction occurring at the surface These results therefore strengthen Maxted and Moon's criticism[2] of Taylor and Pace s results[3]

The results obtained for zinc and cobalt molybdenum oxides were very similar, and each exhibited the 'inversion' found by Klar[4], and also by Beebe and co workers[5] Below about 300° C , deuterium was adsorbed to a smaller extent than hydrogen, whilst above this temperature the adsorption of deuterium was greater than that of hydrogen

With the highly active nickel molybdenum oxide, however, the activated adsorption of deuterium never exceeded that of hydrogen. The rates of adsorption were slightly lower in every case, but, above 218° C after a period of two or three hours, the rates became identical. Apparently the factors influencing the adsorption differences of the hydrogen isotopes are · (1) surface area of the adsorbent for Van der Waals' adsorption, and (2) the chemical constitution of the adsorbent in the case of activated adsorption

The high-temperature heats of adsorption for hydrogen on zinc-molybdenum oxide, cobalt-molybdenum oxide and nickel-molybdenum oxide were 21,400, 31,400 and 21,600 cal. respectively, compared with the corresponding values of 30,100, 34,200 and 31,125 cal for deuterium. These values were calculated from the adsorption isotherms at 400° C and 444° C. Differences in activation energy have also been found

These results are to be published in greater detail in the near future.

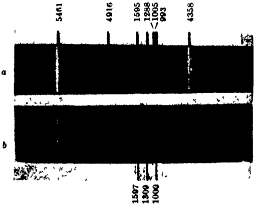
Raman Spectra of Compounds with Three Benzene Rings

IN this investigation we have succeeded for the first time in obtaining the Raman spectra of *o*-diphenyl benzene and *m*-diphenyl benzene. We have studied these compounds with the view of obtaining some evidence about the nature and symmetry of their benzene rings and also to record their Raman lines and to assign their frequencies correctly These two substances are solid at the ordinary temperature and they present the difficulty of showing such powerful fluorescence under the total radiation of the mercury arc that the Raman lines are almost all completely masked, leaving scarcely any trace of such lines on the plate. Using these substances in the molten state and taking other great precautions, we have been able to suppress, as the accompanying photographs show, a good deal of the continuous fluorescent background, which was found to be even more marked in the case of *m*-diphenyl benzene.



a, *o*-DIPHENYL BENZENE, *b*, *m*-DIPHENYL BENZENE

O-diphenyl benzene has yielded 33 new lines not recorded before, at frequencies 3196, 3059, 1608, 1595, 1577, 1503, 1471, 1430, 1288, 1247, 1180, 1158, 1059, 1032, 1005, 993, 874, 839, 774, 744, 708, 708, 615(br.), 558, 521, 501(?), 406, 359, 319, 253, 238(br.), 144(br), 112(br) and 73(br) cm $^{-1}$.

In addition to these frequencies, *o*-diphenyl benzene shows on our plates seven anti-Stokes lines not recorded before, at frequencies 993, 708, 615, 406, 359, 238 and 144 cm $^{-1}$

M-diphenyl benzene, in spite of very marked fluorescence observed on the plates, has also yielded 27 new lines not recorded before. The frequency shifts observed in this case are 3062, 1607, 1597, 1566, 1494, 1453, 1403, 1345, 1309, 1279, 1241(br), 1153, 1098, 1039, 1000, 964, 901, 838, 801, 766, 707, 611, 406, 275(diff), 238(diff), 151(diff and br) and 80(diff and br) cm $^{-1}$

Further investigation is proceeding on these very interesting results, and we hope to give all the details and discussions in a paper which we are offering for publication very soon.

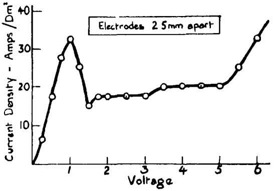
Electrolytic 'Polishing' of Zinc

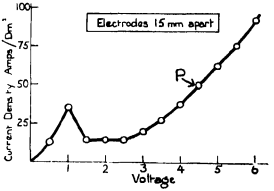
P A JACQUET has described a process whereby 'polished' copper surfaces, resembling in smoothness and brightness those yielded by ordinary mechanical polishing, could be obtained by anodic treatment in a suitable electrolyte, under prescribed conditions of current and E M F [1] He has since extended his method to lead and tin[2] and to aluminium[3], and the same principle has been applied to the polishing of nickel[4], but no work appears to have been published on the electrolytic 'polishing' of zinc

Recently, in the course of an investigation on the oxidation of zinc sheet, we have sought a method of preparation which would avoid production of a flowed or disturbed surface layer such as results from mechanical polishing, and at the same time be free from possible objections of chemical etching, notably the risk of traces of reagent remaining in crevices produced by the etching process itself

Employing a similar electrical circuit to that used in the earlier work, we have obtained quite smooth and bright surfaces from the following procedure. The specimen receives a preliminary abrasion with emery paper followed by de-greasing in benzene or other suitable solvent It is then made the anode (a strip of copper serving as cathode) in an electrolyte consisting of a 25 per cent solution of potassium hydroxide; this is used at room temperature, and is agitated by the passage of a stream of air or nitrogen as an alternative to the rotating anode recommended by Jacquet. Electrical relationships (E.M.F /current-density) are shown in the accompanying graphs for electrode distances of 2·5 mm. and 15 mm. respectively The shape of the curve is similar to the typical curve established by Jacquet for other metals and electrolytes 'Polishing' occurs characteristically, without evolution of gas, in the range represented by the nearly horizontal portion of the curve, that is, at a current density of approximately 16 amp./dm.^{2}, the effective E.M.F. being spread over a wider range at the shorter distance.

At lower and higher E M F values, etching or roughening of the specimen takes place, with gas evolution, but at still higher values (beyond the point *P*) the phenomenon of 'polishing' (now accompanied by gas evolution) reappears. For specimens previously abraded with fine emery paper (finishing with Hubert 0000) as in our experiments, 15 minutes at 6 volts suffices for the electrolytic treatment; coarser initial surfaces can, however, be satisfactorily dealt with in appropriately longer times.





We have followed Jacquet in the use of the term 'polishing'; neither of the alternatives that have been proposed ('brightening' and 'smoothing') is adequate, since each refers to one component only of the process actually involved.

Melting Point of High-Purity Silicon

Hoffmann and Schulze[1] have recently determined the melting point of high purity silicon (99.89 per cent) and of commercial silicon (98 per cent), and give the values 1,411° ± 2° C and 1,409° ± 2° C respectively.

When high-purity silicon was first prepared at the National Physical Laboratory by Tucker[2], I determined the melting point of a very pure sample, but the results were not published. In comparison with the above, the data I obtained are of considerable interest.

The silicon, in granular form, was packed tightly in a silica pot, the top of which was sealed, with a silica thermocouple sheath passing through to a depth of about a quarter of the height from the bottom of the pot. The temperatures of melting and of freezing were measured by means of a calibrated 5/20 rhodium platinum thermocouple.

The results obtained were as follows:

		Temperature in microvolts	
(*a*)	Cooling	8680	
(*b*)	Heating	8685	
(*c*)	Cooling	8681	
(*d*)	Heating	8683	
	Mean value	8682	1,415° C

The analysis of the silicon after the above experiment had been carried out is given below and was the same as that of the original batch of material.

Insoluble	0.01 per cent
Al	0.02
Fe	0.0
Ca	0.02
Silicon (by difference)	99.93

The melting point of silicon of purity 99.93 per cent is therefore given as 1,415° ± 2° C.

The silicon used by Hoffmann and Schulze was slightly less pure (99.89 per cent) and it would therefore be expected that the melting point of that sample, namely, 1,411° ± 2° C, should be a little lower than that described above.

Photochemical Equivalent in Optical Sensitizing

IN a communication to NATURE[1] entitled "Mechanism of Optical Sensitizing of Silver Halides by Dyes", we described briefly some experimental results showing that sensitizing dyes adsorbed to silver halides produce by absorption of light in their own absorption bands decomposition of the silver halide into metallic silver and free halogen. In the presence of adequate halogen acceptors, the dye remains chemically unchanged.

The mechanism of the energy transfer in this process has not yet been explained adequately. G Scheibe[2], following the suggestions of Gaffron, Weiss and others, has applied the idea of quantum summation to dye sensitizing of photographic plates. According to this, large polymeric aggregates of dye molecules may absorb several quanta simultaneously and, in some unexplained fashion, integrate smaller quanta to form larger ones. In some such manner it is suggested that a quantum large enough to decompose silver halide is obtained from smaller quanta absorbed by the dye.

There are a number of reasons from photographic observations and theory which argue against this, but it is evident that a primary experimental datum is the photochemical equivalent. In continuing under improved conditions the experiments referred to in our letter, we have been able to show with both erythrosine, an acid dye, and with polymethine (cyanine) basic dyes, that the values for the photochemical equivalent cluster closely around unity That is to say, for each quantum of light absorbed per dye molecule, one atom of silver is produced, in any event in the initial high efficiency region of the adsorption[1] This result shows that Scheibe's hypothesis is unnecessary, as an explanation of the energetics, and, for the region studied is incorrect

Diffusion in Non-Ideal Media

In 1934[1], it was suggested that the high temperature coefficients frequently found for diffusion processes in biological systems were a simple and necessary concomitant of the high potential energy barriers which prevent free diffusion in such systems It has now been found that the underlying theory can be put into a useful quantitative form

In an ideal diffusion medium, diffusion is a continuous process, and its rate is defined by the classical equation

$$Dm^{\frac{1}{2}} = \text{constant} \tag{1}$$

where D is the diffusion constant and m is the mass of the diffusing molecules In real liquids and solids, diffusion is retarded by potential energy barriers hence of the total number of molecules in a system, only those are free to diffuse which have kinetic energy sufficient to permit passage through the potential energy barriers Hence diffusion alternates with periods of vibration about a mean position

If the simplest possible assumptions are made about such a system, that is, that the potential barriers surrounding the molecules concerned are uniform and do not vary with time, and that all molecules having sufficient energy to diffuse through the potential energy barriers have in fact an equal chance of doing so, then it is easy to prove the following relationships, (2) for molecules diffusing in a concentration gradient, (3) for ions diffusing in a potential gradient

$$Dm^{\frac{1}{2}}Q_{10}^{n} = A \tag{2}$$

$$lQ_{10}^{n} = B, \tag{3}$$

where $n = (T + 10)/10$, T is the absolute temperature, l is the mobility of the ions, and Q_{10} is the ratio of the rates of the diffusion process concerned at the temperatures T and $(T + 10)$ A and B are constants independent of the diffusing species, but varying with temperature and with the nature of the diffusion medium These equations are reasonably satisfactory over a wide range of conditions

Another method of verifying equation (3) is to use it for the calculation of liquid junction potentials If the equation is correct, B/Q_{10}^{n} can be substituted for l If this is carried out in Henderson's procedure, it is found that liquid junction potentials can be calculated if the activities and the Q_{10}'s of the mobilities of the ions are known The difference between the calculated and the observed potentials is of the order of 0 2 millivolts, this is considerably better agreement than is obtained by calculating directly from the mobilities There is no theoretical reason why the calculation based on Q_{10} should be more accurate than that based on mobility, the advantage probably arises from the fact that in the measurement of Q_{10} systematic errors tend to cancel out

Equations (2) and (3) can be applied to biological systems for the elucidation of membrane structure If a membrane behaves as a homogeneous structure towards penetrating molecules, equations similar to (2) and (3) hold It is found that red blood cell membranes are far from homogeneous, whereas *Arbacia* egg membranes are probably homogeneous

Experiments are now being made to obtain similar information for nerve and muscle cells

Isolation of Progesterone and Allopregnanolone from the Adrenal

The presence in the adrenal gland of material possessing progestational activity was reported by Engelhart[1], who obtained lipoid extracts which produced oestrous and progestational effects in the uterus of the immature rabbit Callow and Parkes[2] confirmed these findings and showed that a fractionation of the active materials was possible by the method of Allen and Meyer[3] They suggested, in view of the structure of the substances already isolated from the adrenal cortex, that the material responsible for the progestational activity might be progesterone or a closely allied compound

Using pentane soluble material kindly supplied by N V Organon Oss prepared by extracting ox adrenals by the modified method of Swingle and Pfiffner[4], followed by distribution of the crude extract between pentane and 30 per cent alcohol, we have each succeeded independently in isolating progesterone (m p 121°) and allopregnanol(3) one(20) (m p 198 200° cor) The latter which is without obvious biological activity, occurred in the greater amounts Bioassays carried on throughout the work by one of us (D B), with the kind co operation of Dr A S Parkes suggest that much, if not all, the activity can be accounted for by the progesterone content

Experimental details of the methods used by each of us for the isolation of these compounds will be published independently in full detail shortly

Changes in the Lymph Glands of Tumour-Bearing Mice

DURING experiments in this Institute as previously described[1,2,3], a spindle-celled sarcoma (*Mal. sarcoma* 1) was obtained in a mouse after 133 days' treatment with a carcinogenic compound Mice bearing grafted generations of this tumour showed blood changes to accompany the growth of the grafts, and on five occasions cell-free filtrates giving rise to sarcomas resembling the parent tumour were obtained and grafted for many generations In the 122nd generation of the original sarcoma, a cell-free filtrate of this tumour, together with blood from the mouse bearing the grafted generation, was introduced into an irradiated mouse, which produced a sarcoma (*Mal Fil* 6) at the site of inoculation This tumour and its descendants have provided the material for the experiments to be described

Mice bearing these tumours show the following changes:

(1) In many, the lymphoid tissue becomes involved in a widespread neoplastic change affecting the glands of axillæ, groin, lumbar and mesenteric regions The degree of involvement shows no relation to the proximity of the grafted tumour. Microscopic examination of the glands shows four conditions, namely:

(*a*) The gland may differ little if at all from normal.

(*b*) Changes similar to those seen in mice after X-radiation, or during induction of a sarcoma by a chemical agent[4,5].

(*c*) The lymphoid tissue is more or less wholly replaced by spindle-cells similar to those of the tumour grafts In these cases, such glands may or may not show enlargement Minute and remote glands giving no macroscopic evidence of change may be composed of tumour cells Comparison of sections suggest that this change begins at the periphery, for the medulla may be entirely surrounded by a band of large, pale cells which extend down the trabeculæ in close masses The appearances do not suggest the spread of these cells from a metastatic focus They seem rather compatible with some further development of process (*b*) The simultaneous changes in glands on both sides of the body are difficult to explain by any process of metastasis.

(*d*) The normal lymphoid cells appear to undergo hyperplasia with enlargement of the glands, suggesting a lymphosarcomatous change difficult to explain

(2) Subcutaneous injections of blood from these mice produce sarcomas—one of which is now in its sixth grafted generation

(3) Portions of glands, or whole glands from mice bearing grafted generations of *Mal. Fil.* 6 and other tumours similarly obtained, when grafted into mice, induce tumours at site of inoculation—which sarcomas have been propagated by grafting. In selecting glands for transplantation those appearing to be enlarged were avoided, and, where microscopic examination was made of other halves of glands grafted, many of these appeared normal. Hence the capacity for neoplastic growth on transplantation does not seem to depend on previous sarcomatous changes as described under 1(c). It might be suggested that the process of transplantation *per se* encourages growth[6]. The rapidity of changes involved is remarkable—a lymph gland transferred from mouse *A* to mouse *B* five days after grafting the sarcoma in *A* has been found fifteen days later to have produced a tumour histologically similar to the parent graft in *A*. Normal mice grafted with normal glands have not developed tumours.

Similar results have also been obtained with the mouse sarcoma *S* 37.

The factors concerned in these changes in lymph glands are under investigation here, and quantitative estimations of iron in such glands are being carried out by Mr Warren The metabolism of lymph glands is being examined by Mrs Boyland

These inquiries have been assisted by grants from the International Cancer Research Foundation, the British Empire Cancer Campaign, and the Finney-Howell Research Foundation.

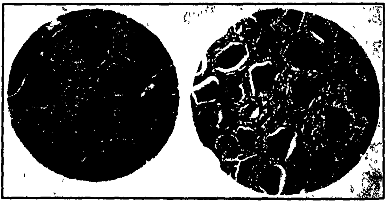
Assay of Thyrotropic Hormone

THE thyroid gland of the grass snake (*Tropidonotus natrix*) is readily affected by subcutaneous injections of small amounts of thyrotropic hormone, showing hyperplasia and a strong colloid loss As it presents a very constant histological picture under conditions where the thyroids of animals such as rats and guinea pigs often show considerable histological variation, this is suggested as a possible means of assay of thyrotropic hormone. Although effective at temperatures so low as 13° C., thyrotropic hormone reacts more strongly at 24° C. Grass snakes are inexpensive and easily handled in a laboratory.



THYROID OF CONTROL NON-HIBERNATING SNAKE (*a*), AND OF A SIMILAR SNAKE INJECTED WITH THYROTROPIC HORMONE (*b*).

The accompanying photomicrographs show the thyroid of a control non hibernating snake kept at 24° C (*a*) and the gland of a snake kept under similar conditions which had been twice injected with half a unit of thyrotropic hormone at 24 hour intervals, and killed twenty four hours after the final injection (*b*)

Cholinesterase at the End-Plates of Voluntary Muscle after Nerve Degeneration

The concentration of cholinesterase is increased in voluntary muscle of guinea pigs after nerve degeneration[1] It has been suggested[2] that this increase results from the considerably decreased volume (V) of muscle fibres The number of fibres and end plates remains constant at least during the period examined (five weeks) Whilst the volume of muscle fibres decreases the unchanged volume of end plates becomes relatively more important Due to the high concentration of the enzyme at the end plates a change in the relation V end plates/V muscle fibres in favour of V end plates must produce an increase of the enzyme concentration of the whole muscle as taken for the determinations

We have measured the relation between the volume of normal and denervated muscle fibres and determined at the same time the concentration of the enzyme Two weeks after cutting the sciatic nerve of guinea pigs the increase of the concentration of cholinesterase is approximately inversely proportional to the decrease of volume of the denervated muscle fibre This indicates that the concentration of enzyme at the end plates at this time is nearly unchanged Four to five weeks after denervation the diminution of volume of the denervated muscle fibre is more important than the increase of the enzyme concentration The concentration at the end plates at this date seems to be a little smaller than in normal end plates But even then there is still a very high concentration

In the peripheral part of the cut sciatic the concentration of cholinesterase after two weeks is decreased (about 30 per cent) whereas in the neuroma formed at the central end of the cut sciatic the concentration increases to a value which is twice as high as in the normal nerve[3] The endings of the nerve fibres in muscle at this date have disappeared These experiments provide evidence that the enzyme is localized at a high concentration in the end plates of muscle and not in the endings of the nerve fibres

This work has been made possible by a grant of the Ella Sachs Plotz Foundation

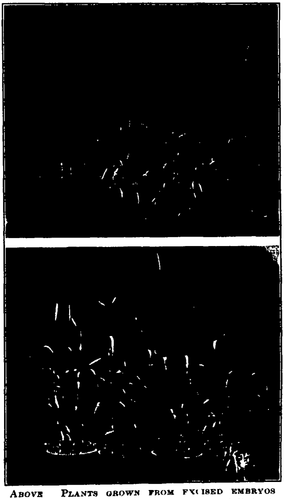
Vernalization of Excised Embryos

In a previous letter[1] attention was directed to the fact that the process of vernalization could be carried out successfully on excised embryos of winter rye var Petkus (fuller information has been published elsewhere[2]) The embryos in the case referred to were removed from grains previously soaked for 5 hr in a sterilizing solution and were kept on an agar medium containing nutrient salts and glucose

More recent work has shown that even during the first few hours after soaking far reaching changes occur in the grain leading to exchanges between aleurone layer endosperm and embryo resulting in large variations in growth of roots and coleoptile The experiment here reported investigates the possible role of such exchanges by utilizing embryos excised from the dry grain Such exchanges were found to be inoperative in vernalization On the other hand the presence of carbohydrate supply (3 per cent sucrose) has been found to be essential



Above Plants grown from excised embryos kept at 1° C for six weeks on nutrient agar without carbohydrate

Below Plants grown from similar embryos treated in the same way but on nutrient agar containing 3 per cent sucrose

In the accompanying photographs plants are shown grown from excised embryos removed after different periods of soaking, one set placed on agar and nutrient salts only, the other set receiving 3 per cent sucrose in addition All were kept at 1° C for six weeks, at the end of which period sugar was added to the control set now kept at room temperature until large enough to transplant to soil It will be seen that, in the absence of sugar during the low temperature exposure (upper photograph) almost complete failure of vernalization has resulted Clearly therefore the vernalization effect is concerned with some change in the absorbed carbohydrate occurring at low temperature only (lower photograph)

Further work will be undertaken with different concentrations of various sugars and also on the effect of omitting inorganic nitrogen from the culture medium

Discovery of *Cœloplana sp* at Krusadi Island Marine Biological Station, Madras

AFTER the silver jubilee session of the Indian Science Congress in Calcutta, to which I was a delegate, was concluded, I went down to the south of India to the Marine Biological Station Krusadi Island, at the kind invitation of the director of fisheries for Madras, Dr Sundara Raj to study the fauna of that coral island

While there I was fortunate to collect a single specimen of *Cœloplana*, which I detected crawling in a dish containing seaweeds, chiefly *Halimeda opuntiades* The specimen was about 5 mm in length translucent and faintly suffused with green to tone in with the weed on which it was living I made several observations on and sketches of the living animal, but was unable to preserve it as it fragmented when I attempted to kill it with corrosive sublimate Unfortunately, I had to leave for Colombo the next day and was unable to obtain and study any further material

The animal resembles *C bocki* Komai, described from Japan, but certain differences compel me to think that it represents a new species The work of describing the animal has been entrusted to Dr D W Devanesan, assistant director of fisheries for Madras, and his research assistant, Mr S Varadarajan I have since heard that these two workers have secured a good deal more material and we may hope for a full description before long In the mean time, it seems desirable to place on record this interesting find, the first from Indian waters, and in a locality far removed from any other in which the genus has been found The species is evidently not uncommon and the clue to its habitat may be useful to others who may have the opportunity of biological work in the tropics

Function of the 'Gills' in Mosquito Larvæ

IT has been assumed until quite recently that the 'gills, or anal papillæ, of mosquito larvæ serve for respiration and I accepted this view in a previous publication[1], though with some misgivings in view of Dr Wigglesworth's demonstration[2], that the respiratory function is at most secondary

Wigglesworth (1938)[3] has summed up work of his own and of others and has shown beyond doubt not only that the main function of the gills is the absorption of chloride but also that the size of these structures in a given species of mosquito is largely governed by the concentration of chloride in the water, the gills being considerably larger in water of low chloride content than when the concentration of chloride is comparatively high

Though, however, Wigglesworth mentions that this phenomenon provides an explanation for the large sausage shaped type of gill characteristic of larvæ breeding in small containers (tree holes, plant axils, etc) and, by inference for the small rounded gills of those which breed in saline waters, he has omitted to note that it also explains the anomalous case of those larvæ which breed in small containers but which are predaceous These latter have very short rounded papillæ (ref 1, p 21) instead of the large sausage shaped type which is found in nearly all other species occurring in small containers In the light of the discovery that the chief function of the anal papillæ is to absorb chloride, the explanation of this apparent anomaly becomes obvious predaceous larvæ obtain their chloride from the bodies of their victims and thus do not require large gills wherewith to absorb it independently

A Curious Atmospheric Phenomenon

ON July 23, at 5 p m , while visiting Ranelagh, a friend and I were sitting in the small temple which is at the highest point in the grounds It was a bright day with little wind, but there were haze and some cloud I do not know the bearings from this temple, but considering a line at right angles to the door of the temple as zero, the phenomenon to be described occurred at an angle of azimuth of 45° or 50° to our left, which may have been E S E

The occurrence was first noticed at 5 p m and went on until 5 15 and later, and was again seen at 6 15 from another station at the general ground level

What we saw was a tall and very narrow, vertical, grey column subtending a vertical angle of 20° or 25° In the foreground about a quarter of a mile away were tall trees and the column appeared behind these at perhaps a third of a mile away from us There was a slight wave motion up the column, the amplitude of the waves being say two or three diameters of the column, which was perhaps fifty or more diameters high The diameter was constant all the way up The column persisted for a time always in the same place except when there were two (? three) columns separated by an angle of azimuth of say 2° or 3°

When the column disappeared, as it did frequently, it did so along its whole height at the same time, and formed again suddenly along its whole height Occasionally a top short length would break off, float away and disappear

I directed the attention of two women (strangers who happened to visit the temple) to the occurrence and they too saw it easily, so in all four saw it

The only cause I can think of is that there was a whirlwind, or a series of whirlwinds which concentrated the haze Smoke seems unlikely The straightness, verticality, uniformity of diameter, constant position and repeated occurrence were most marked

It would be interesting to know if such a phenomenon has been seen before and what explanation, if any, has been suggested

Points from Foregoing Letters

A GRAPH showing the variation with temperature of the intensity of the magnetic field needed for the onset of resistance in very thin superconducting films of mercury (400 1000 and 10,000 A approximately) is submitted by Dr F T S Appleyard and A D Misener The intensity of the field changes by a factor of more than fifteen on passing from the thinnest to the thickest film

Drs J G Daunt and K Mendelssohn find that the film of liquid helium II which forms on solid surfaces is about 5×10^{-4} cm thick, and that the heat transport through the film is a transfer of mass They conclude that the rate of transfer depends only on the thermal state of liquid helium II

Using five counters separated by various thicknesses of air and lead, Miss Z Wasiutyńska and Prof L Wertenstein have sought for evidence of neutron proton exchange phenomena in cosmic rays They conclude that if the particles constituting the bulk of the penetrating component give rise to any exchange effect, the mean free path in lead for this effect is much longer than 30 cm , and they calculate that the relative number of protons present in cosmic penetrating radiation must be very small

The difference between the absorption of hydrogen and of deuterium on promoted molybdenum oxides is found by J H Hudson and G Ogden to vary with temperature and type of promoter (zinc, nickel or cobalt) At 77° K the deuterium is absorbed to a greater extent than hydrogen by all three absorbents , at 218° C the absorption of the deuterium is lower than in the case of zinc and cobalt molybdenum whilst above 300° the absorption again becomes greater

Photographs of Raman spectra of *ortho* and *meta* diphenyl benzene in the molten state are submitted by Prof S K Mukerji Thirty three new lines were recorded for the *ortho* compound and 27 new lines for the *meta* compound, and these may throw some light on the nature of the symmetry of the benzene rings in their structure

Dr W H J Vernon and E G Stroud describe a method for obtaining 'polished surfaces of zinc (comparable in smoothness and brightness with those produced by mechanical polishing) by means of anodic treatment in an aqueous solution of potassium hydroxide under prescribed conditions of current density and E M F

The melting point of a high-purity silicon sample (99 93 per cent) was found by Dr M L V Gayler to be 1 415 C this being 4° higher than that recently found by Hoffmann and Schulze for a sample of slightly lower purity

Measurements of the photochemical equivalent in the optical sensitizing of silver halides by dyes have been made by Dr S E Sheppard Dr R H Lambert and R D Walker The absorption of one quantum of light per dye molecule gives one atom of silver A quantum equivalent of unity is held to contradict the hypothesis of quantum summation for the process

Formulæ for molecular diffusion in a concentration gradient and for ions diffusing in a potential gradient are submitted by Dr J F Danielli These equations, he states are reasonably satisfactory over a wide range of conditions and may be used to indicate whether biological membranes such as egg membranes and those of the red blood cells are homogeneous or not

D Beall and Prof T Reichstein have each isolated progesterone and allopregnanolone from ox adrenal concentrates

Changes in the lymphatic tissue in rats which have developed a tumour, originally induced by a cancer producing substance are described by Dr Dorothy Parsons The tumour can be produced in other rats by transplantation of a lymph gland or by injection of blood and cell free filtrates from tumour bearing animals

Photomicrographs of thyroid gland sections of the grass snake, showing changes brought about by injection of small amounts of thyrotropic hormone are submitted by Miss E M Mason who suggests that the effect observed may be suitable for the biological assay of the hormone

Following upon the cutting and destruction of the sciatic nerve, the concentration of the enzyme cholinesterase at the end plates of the voluntary muscle of guinea pigs is found by R Couteaux and D Nachmansohn to decrease in inverse proportion to the volume of the muscle This indicates that the enzyme is localized at a high concentration in the end plates of the muscle and not in the endings of the nerve fibres

Photographs of rye plants obtained from embryos excised from seeds and grown after keeping at 1° C for six weeks on agar plus nutrient salts, with and without the addition of 3 per cent sugar solution, are submitted by Prof F G Gregory and R S de Ropp They show that in the absence of sugar during the low temperature exposure, almost complete failure of vernalization results

Research Items

Viking Figure Head from the Scheldt

THE wooden figure head from a Viking ship purchased by the British Museum (Bloomsbury) with the aid of grants from the National Art Collections Fund, and regarded as the most important relic of the Vikings outside Scandinavia has recently been described and figured by Mr T D Kendrick (*Brit Mus Quart*, 12 3, 1938) It is the figure head or stern post of a Viking ship, made of oak and measuring four feet nine inches in length It was found about two years ago with ship s timbers during dredging operations in the River Scheldt at Appels, near Termonde, Belgium The carving consists of a beaked head on a long neck, with a perforated tenon at the end It is the only example of the zoomorphic terminals frequently mentioned in the Sagas and represented in the sculptures on Scandinavian tomb stones It is dated tentatively at not later than A D 800 Its attribution, it is anticipated, will be a matter of much discussion It is obviously north German work, and may be Danish, but that it is Norse is unlikely It bears only a distant relationship to the carving which adorned the Norwegian ships, while on structural and morphological grounds it can be shown that it could not have adorned the prow or stern of a vessel of the Oseberg or Gokstad kind While there is nothing precisely like it in Danish archæology it has to be remembered that little or nothing is known of Danish boats, while there is strong probability that a Viking ship sunk off Termonde would be Danish Not only did the Danes for long assail the Frisian coast but they also had a base at the mouth of the Scheldt If this attribution should be correct the Termonde carving is the only considerable fragment that has survived of the ships in which the Danes attacked the Low Countries and the coasts of England

Navaho Ceremonial

IN a study of the agricultural and hunting methods of the Navaho of Arizona and New Mexico, Mr W W Hill points out the unusual amount of ritual that has been integrated in the affairs of everyday life among this people (*Yale Univ Pub Anthrop*, No 18, 1938) To understand their reasons for this, regard must be paid to the salient physical conditions of the Navaho country The difficulties of the physical background, due to its aridity and the distribution and quantity of rainfall, have been overcome by the Navaho in two ways first by the practical adjustment of agricultural methods, and second by incorporation into the agricultural round of a series of ceremonies, which attempt to realize for the individual a control over phenomena that actually he cannot control So in hunting, which was the second most important economic pursuit of the Navaho next to agriculture, they practised a ritual and a non ritual form They believed that game, when killed, did not die but returned to its own country, while they themselves were under the observation of the Talking Gods Hence they were careful to observe all ritual and taboos The observance of ritual made it possible for them to accomplish more than on ordinary occasions For example, in the Wolf Way of hunting they actually came to possess many of the attributes of the wolf, including his prowess in the hunt A peculiar feature of the ritual hunt was the complete reversal of the psychology of the participants Their demeanour, habitually gay, became dour, and no joking or levity was permitted In agriculture the ceremonies were definitely magical and religious in content but in contrast to the bulk of Navaho ritual, they were primarily esoteric in character As attributes of agricultural procedure, they took a role of vital importance in every stage of cultivation and they were most often found interwoven with the actual procedure at points where it had failed to meet the necessities of an inhospitable environment and served to compensate for the lack of technical development

Orthopædic Aspects of Sciatica

DR ARTHUR WESSON (*Reports on Chronic Rheumatic Diseases*, No 4, 1938 H K Lewis) deprecates the view that sciatica indicates inflammation of the sciatic nerve, and maintains that the so called sciatic pain is a referred pain from pathological conditions in the muscles, ligaments and lumbo sacral and sacro iliac joints He describes three main groups of sciatica The first two groups have in common a positive Lasègue s sign and spinal deformity, while in Group III these signs are absent The characteristic features of Group I, which is due mainly to acute and chronic trauma are pain, deformity and lumbo sacral tenderness, and the treatment consists in restoration of alignment, restoration of normal muscle balance and maintenance of full mobility The characteristic features of Group II, which is due to a chronic muscle imbalance, arising from postural and occupational causes, are pain of a more gradual onset, deep tenderness in the area between the iliac crest and great trochanter due to changes in the regional muscles, marked weakness in the abductor muscles of the hip and a functional scoliosis The treatment of this group consists in the production of muscular relaxation and restoration of normal muscle balance

Statistics of the Halibut Fishery

DR P JESPERSON has recently given a comprehensive statistical survey of the halibut fishery in the waters round the Faroes, Iceland and Greenland (*Meddelelser fra Kommissionen for Danmarks Fiskeri og Havundersøgelser*, Serie Fiskeri, 10, No 5) The 27 tables and 20 figures show the changes in the yield of the Faroese and Icelandic fishery since the year 1906 and of the Greenland fishery since 1928 The proportions of the total yield of the fishery taken by different countries are given and it can be seen that in all three areas the English catch greatly exceeds that of other countries Scotland takes second place in Faroese waters 1907 and 1908 and the immediate post War years of 1922 and 1923 were 'peak periods' in the fisheries of both the Iceland and Faroese areas, and each of these peaks has been followed by a marked and steady decline in the total yield of the fishery The total yield after the peak of 1922 and 1923 reached a minimum in 1929 and 1930 in the Icelandic and Faroese waters, and was thereafter followed by a fairly steady increase in the Faroese fishery and a slight one in the Icelandic fishery. Data concerning the Greenland fishery were obtainable only from the year 1928. The year 1929 showed the greatest total yield, since when there has been a decline so that in 1935 the total catch amounted to only half that of 1929. The statement that "these fluctuations in the catches are certainly due more to accidental circumstances connected with the fishery than to any change in the size of the fish stock" may be some reassurance, but the figures of the statistical tables and the graphs which Dr. Jespersen has prepared from them certainly do not present the picture of a stock of fish which is being rationally exploited.

The Cultivated Mushroom

No plant taxes the skill of the gardener so much as the common mushroom; its cropping is often erratic, even with expert commercial treatment. Miss D. M. Cayley has experimented with various composts for the growth of several kinds of wild and cultivated mushrooms (*J. Roy. Hort. Soc.*, 63, Pt. 7, 325–333; July 1938). A loose mixture of chopped straw, chopped hay, crushed oats and sand, watered with a solution of sulphate of ammonia, was found suitable for spawn production. Cultivated mushrooms would produce fruiting bodies upon a wide variety of fermented and unfermented composts. Most of the wild species, however, would not fruit upon artificial composts, but a kind of mushroom which grows around old hay stacks provides an exception. It can be grown upon a simple, cheap compost of naturally rotted material, and offers considerable possibilities for commercial development. Miss Cayley also describes (*Gard. Chron.*, July 16) the history of mushroom cultivation. Marchant le Père was apparently the first to discover, in 1678, the mycelium of the organism, and in 1707 Tournefort first described its horticultural propagation. Other records bring the history to modern times.

Early Echinoderms

Two new echinoids (*Aulechinus* and *Ectinechinus*) from the Upper Ordovician of Girvan are described by E. W. MacBride and W. K. Spencer (*Phil. Trans. Roy. Soc.*, B, 229, 91; 1938). Some of their features recall those seen in the early stages of development of living echinoids, such as the undivided or incompletely divided ambulacral pores, the arrangement of the plates on the peristome, and the incomplete radial symmetry of the apical disk due to the presence of only one inter-radial plate, the madreporite. The test was thin and flexible with two columns of ambulacral and seven to nine of interambulacral plates in each area. The pores in the ambulacral plates are near the per-radial line. A striking feature is that the radial water vessel was enclosed in the test, thus resembling the Asterozoa. The lantern is of a simple type, consisting of jaws and teeth only, and there are no auricles. In the periproct there is an anal pyramid with valvular plates—a character previously unknown in the Echinoidea. Both genera are regular forms, but one (*Ectinechinus*) is stated to be elongate, but with the plane of symmetry different from that in the heart urchins. Even more remarkable than the echinoids is *Eothuria* which, although resembling in many respects the two Echinoids, is regarded as a holothurian, since it is without ocular plates, and possesses five pairs of oral plates instead of jaws. Unlike other holothurians *Eothuria* has a complete test formed of thin plates, a condition comparable with the post-larval stage of *Cucumaria*. The pores in the ambulacral plates differ from those of the echinoids in having many openings.

Lead-Uranium-Thorium Ratio in Cleveite

RECENT analyses of different layers of crystals of uraninite show that the composition may not be uniform throughout a single crystal. Ruth Bakken and Ellen Gleditsch have now examined a single cleveite crystal from Auselmyren in Norway (*Amer. J. Sci.*, 95–106; 1938). Analyses were made of yellow and reddish alteration products (I), adherent gangue material (II), outer layer of the black lustrous cleveite (III), middle layer (IV), and core (V). It is interesting to find that PbO, which is about 13 per cent in V–III, rises to more than 20 per cent in I. Iron oxide similarly rises from about 1 per cent to nearly 4. ThO_2 varies but little in V–III, but is more than doubled in I. Uranium, on the other hand, shows a marked decrease in I. From III to V the colour deepens and the ratio UO_3/UO_2 increases from 1.35 to 1.48. The lead ratios and corresponding (approximate and uncorrected) ages are:

	III	IV	V	Average
$\frac{Pb}{U + 0.36\ Th}$	0.1668	0.1703	0.1721	0.1702
Millions of years	1283	1294	1308	1293

In a similar investigation of a Canadian uraninite from Wilberforce, Alter and Youll (*J. Amer. Chem. Soc.*, 390; 1937) found the lead ratios for the outer and middle layers and core to be 0.1668, 0.1678 and 0.1864 respectively.

Thixotropy

SOME new experiments on thixotropy have recently been described by C. W. Correns and H. G. F. Winkler (*Naturwiss.*, 26, 517; 1938). Powders of a known nuclear size (microscopic and sub-microscopic) were placed in tubes with different quantities of liquids. The degree of thixotropy is given by the ratio of the volume of liquid to the volume of solid for which the system after one minute's rest just shows no liquid flow when the tube is inverted, though the system is liquid when shaken. It was found that of the particles examined, those which were flat or rod-shaped showed thixotropy in water. The following substances of this type were used: kaolin, halloysite, metahalloysite, muscovite, glauconite, graphite, molybdenum glance and tremolite. Quartz, felspar and fluorspar, on the other hand, are approximately isometric, and do not show the phenomenon in water. The degree of thixotropy is greater the finer the particles. The presence of electrolytes is not necessary for the occurrence of the phenomenon. Their effect varies and does not follow the coagulation series. Thixotropy occurs not only with aqueous sols, but also in organic media. In fact, some substances, such as quartz, felspar and fluorspar, which do not show the phenomenon in water, do so in benzene provided the particles are of the right size. It may be concluded that every substance, if the particles are sufficiently fine, will show thixotropy in a suitable liquid.

Mechanism of Mutarotation

R Kuhn and L Birkofer have recently discussed the catalytic reduction of glucosides derived from secondary bases and the bearing of their experimental results on the theory of mutarotation (*Ber deutsch chem Gesells* July) Jacobson and Stelzner regarded the mutarotation of sugars as a process of oxo cyclo desmotropy, or ring chain tautomerism, which involves the change from one ring structure to another through an intermediate open form, in which a doubly linked oxygen atom appears Since the resulting carbonyl group is readily reduced by the addition of two hydrogen atoms, it would appear that the mutarotation of a sugar derivative is intimately associated with easy reducibility Thus the alkyl glucosides and the fully acetylated hexoses, which do not exhibit mutarotation, cannot be reduced in the same way as the free hexoses The authors have already described (*Ber* of March) two compounds namely, the *d* glucosides of piperidine and dibenzyl amine, which unexpectedly exhibit mutarotation As derivatives of secondary amines they are incapable of yielding Schiff's bases, and it would be reasonable therefore, to suppose that they would not be easily reduced In fact under the usual conditions reduction at 100° C leads only to the formation of free base and *d* sorbitol, but by keeping the temperature below 75° C and using nickel as catalyst it has been found possible to isolate N 1′ sorbityl piperidine, so that mutarotation and alcoholic reduction are again shown to be interdependent Further explanation of the mechanism of mutarotation is furnished by a study of the glucoside derived from dibenzylamine, which has an extremely low mutarotation velocity The latter was enormously increased by the addition of water and to an even greater extent by hydrochloric acid Thus the authors conclude that in such cases either bases or salts must be formed before mutarotation can occur, so that it is not the glucoside itself but rather its cations which undergo this transformation This seems to bring their views into harmony with those expressed by Lowry

Thermal Data for Organic Compounds

THE heats of combustion of some compounds which are important in carbohydrate metabolism have been determined by means of the bomb calorimeter by H M Huffman and S W Fox (*J Amer Chem Soc*, 60 1400, 1938) From the results at 25°, the values of the heats of formation (ΔH) and the free energies of formation (ΔF) in k cal are calculated to be as follows

	$-\Delta H$	$-\Delta F$
Fumaric acid	194 88	157 23
Maleic acid	189 45	151 32
Succinic acid	225 66	179 86
α d Glucose	305 73	218 72
α-d Glucose hydrate	376 52	275 76
β-d Glucose	304 23	218 32

Sulphur Dioxide

SOME thermal properties of sulphur dioxide have been accurately measured by W F Giauque and C C Stephenson (*J Amer Chem Soc*, 60, 1389, 1938) The melting and boiling points were found to be 197 64° K and 263 08° K, respectively (0° C = 273 10° K) The heats of fusion and evaporation per mol are 1769 1 gm cal and 5960 gm cal, respectively The vapour pressures were determined and represented by an equation From calorimetric measurements, the entropy of the gas at the boiling point was found to be 59 23 units per mol, which agrees with the value found from spectroscopic data, showing that the entropy approaches zero at the absolute zero The bond angle (between S and O) in the sulphur dioxide molecule is calculated as 129 ± 4°, with the S—O distance as 1 46 ± 0 02 A

Galerkin's Method in Differential Equations

THIS method was given by V G Galerkin in his treatise Rods and Plates' (Vestnik Ingeneroff) so long ago as 1915 but owing to language difficulties is little known in Great Britain The account by Prof W J Duncan (*Aeronautical Res Com Rep and Mem*, No 1798, 1937) will therefore serve a useful purpose The method starts by choosing a certain number of functions which satisfy the given boundary conditions, and taking a linear combination of these, with coefficients chosen so that the mean square error shall be as small as possible In practice, the minimum condition gives a set of simultaneous linear algebraic equations The method is particularly suitable for mechanical problems concerning elasticity or oscillations, such as occur in engineering and aerodynamics The equations obtained have a direct dynamical significance, namely, that of the vanishing of the virtual work in an appropriate displacement, and the method itself can be regarded as equivalent to the employment of Lagrange s dynamical equations with a special co ordinate system It is interesting to notice that, to make the best choice of certain multipliers it is necessary to know the physical meaning of the differential equation to be solved It is probable that the Galerkin method can be applied to every mechanical problem concerning elastic or other continuously deformable bodies, as well as to ordinary problems in the numerical solution of differential equations

Constants of Star-Streams

SOME years ago, Prof W M Smart published a paper concerning the constants of the star streams derived from the photographic proper motions of stars in which an analysis was made of the photographic proper motions of 3,029 stars (*Mon Not Roy Soc*, 87, 122, 1926) The plates, on which the determination of proper motions was based, were mainly parallax plates, taken with the Sheepshanks equatorial of Cambridge Observatory The material for a paper by Prof W M Smart and T R Tannahill (*Mon Not Roy Astro Soc*, 98, 7, May 1938) is derived from the measurement of similar Cambridge plates of 21 regions, and the photographic proper motions of the 1775 stars have been analysed according to the two stream theory by Eddington s method Stenquist found that there was a rapid increase of the probable errors for stars beyond a certain distance from the centre of each region, and in accordance with his procedure the present authors have rejected stars with images in the corner of plates Although the intervals are rather longer, on the average, than those used in the first paper, it is considered that the above refinement has so reduced the probable error that they are practically the same in both cases It was concluded in the first paper that the average probable error of the centennial proper motion was ±0 4″ in each co-ordinate. The analysis shows that 909 stars belong to Drift i and 794 to Drift ii, and the position of the vertex in galactic co ordinates is 337°, −1 4°. The solar motion with respect to the effective total of stars is directed towards the position, R.A 261° 1, Dec + 42°·5.

Chemistry of Cements

AN international symposium on the chemistry of cements, organized by the Royal Swedish Institute for Engineering Research and the Swedish Cement Association, was held in Stockholm on July 6–8 and attended by representatives from Great Britain, Canada, the United States and many of the European countries A short tour was arranged to precede the meeting, to enable visitors from abroad to see the cement and concrete industry in southern and central Sweden

The meeting, which was limited to a discussion of scientific problems and from which questions of testing and utilization were excluded, was the first international discussion of its type since the meeting held in London by the Faraday Society in 1918 A comparison of the papers presented at these two meetings shows how great have been the advances made in fundamental knowledge during the last twenty years?

After an opening address by Prof A F Enstrom, president of the Royal Swedish Institute for Engineering Research, two introductory lectures were given, one by Prof The Svedberg on 'The Study of Giant Molecules by Means of Ultra centrifugal Sedimentation, Diffusion and Electrophoresis , and the other by Prof A Hedvall on "Reactions between Substances in Solid State with Special Regard to Systems Containing Silica" At an early stage in the subsequent proceedings of the congress an act of homage to the memory of Le Chatelier was paid in the form of the following telegram sent to the Sorbonne, Paris

"A l'occasion du 'Symposium on the Chemistry of Cements' tenu à Stockholm le 6–8 Juillet sur invitation de L'Académie Royale des Sciences Polytechniques et de la Société Suédoise du Ciment, les participants au Congrès, venus d'Allemagne, d'Angleterre, de Belgique, du Canada, du Danemark, des Etats Unis, de Finlande, de Norvège, de Pologne, de Suède et de Suisse sont heureux d'accomplir un devoir de profonde reconnaissance en rendant hommage à la mémoire du grand savant français Henry le Chatelier, qui par son génie a tant contribué à la prospérité de la Science chimique et de la Technique en frayant spécialement la voie à la Chimie des Ciments par ses travaux proéminents et fondamentaux "

The papers presented to the congress, which together with the discussion will later be published in one volume by the Royal Swedish Institute for Engineering Research, were as follows 'Constitution of Portland Cement Clinker" by Dr R H Bogue (Bureau of Standards, U S A), "X rays and Cement Chemistry" by Dr W Bussem (Kaiser-Wilhelm Institüt für Silikatforschung, Germany), "Calcium Aluminate and Silicate Hydrates" by Mr G E. Bessey (Building Research Station, Great Britain), 'The Calcium Aluminate Complex Salts" by Mr F E. Jones (Building Research Station, Great Britain), "Portland Cement and Hydrothermal Reactions" by Prof T Thorvaldson (University of Saskatchewan, Canada), "Reactions of Portland Cement with Water" by Prof P Schläpfer (Technische Hochschule, Zürich, Switzerland), "The Chemistry of Retarders and Accelerators" by Dr L Forsén (Skanska Cementaktiebolaget, Limhamn, Sweden), 'Constitution of Aluminous Cement Clinker" by Dr N Sundius (Geological Survey of Sweden), Reactions of Aluminous Cement with Water" by Dr G Assarsson (Geological Survey of Sweden), 'Chemistry of Pozzolanas ' by Dr F M Lea (Building Research Station, Great Britain) and "Physical Structure of Hydrated Cements ' by Mr S Giertz Hedström (Royal Swedish Institute for Engineering Research, Stockholm) The discussions, including written contributions submitted by authors unable to be present, were maintained at the high level set by the papers

Particular interest attached to the glass phase present in Portland cement clinker Under very rapid cooling conditions, homogeneous structureless glasses can be obtained, but, with rather less rapid quenching, products are obtained which, although apparently glassy, give a strong X ray diffraction pattern This seems to be identical for glasses containing lime, silica and alumina, or lime, silica and ferric oxide, and also almost identical with that of the compound $3CaO\ Al_2O_3$, which has been found to have a structure of the perovskite type The suggestion was made by Bogue and Brownmiller that this pattern may be attributed to the formation of oxygen polyhedra, giving rise to the periodicity necessary for a strong X ray pattern, but that the accessory atoms are still randomly distributed, and only when cooling is slower do these atoms take up definite lattice positions and give rise to crystalline compounds It has been suggested that the patterns may be due to sub microscopic crystallization of alumina and iron compounds of very similar structure of the perovskite type While the compound $3CaO\ Al_2O_3$ is well known, however, the corresponding compound $3CaO\ Fe_2O_3$ has not been found in either binary or ternary systems containing lime and ferric oxide

No hydrated calcium alumino silicates of the more basic type had previously been prepared in the laboratory, but Bussem reported that evidence of the formation of compounds $3CaO\ Al_2O_3$, $2SiO_2$ aq and $2CaO\ Al_2O_3\ SiO_2$ aq in the quaternary system $CaO-Al_2O_3-SiO_2-H_2O$ have now been obtained It was evident that knowledge of the ternary systems involved in this quaternary system is now sufficiently far advanced to render a systematic investigation of it possible The complexity of the crystalline calcium silicate hydrates is indicated by the finding that, in addition to the naturally occurring mineral hillebrandite, $2CaO\ SiO_2H_2O$ three other crystalline hydrated dicalcium silicates, differing in their X ray pattern and optical properties, can be prepared by the action of high pressure steam on the anhydrous compound It is also noteworthy that, though no more basic compound than that with a 2 1 $CaO\ SiO_2$ ratio has been obtained from aqueous reactions, a hydrated crystalline tricalcium silicate can be obtained from the corresponding anhydrous compound by similar means

The general subject of the retardation of chemical reactions has been discussed recently by Prof K. V Bailey in his book "The Retardation of Chemical Reactions" The new work on the action of retarders and accelerators on Portland cement, reported by Dr L Forsén, has shown that their effects are dependent on the rate at which they cause precipitation of alumina from solution, and that the action of a wide variety of substances can be explained in this manner

The mineralogy of aluminous cement is complex, and the nature of the iron compounds present is still controversial A large part of the ferrous iron is found in that portion of the clinker which solidifies last, forming a dark and usually opaque glass X-ray evidence suggests that free ferrous oxide is present as wustite in sub-microscopic form, thus accounting for the high refractive index of the glass The unstable form of the compound $5CaO\ 3Al_2O_3$ (probably more correctly formulated as $12CaO\ 7Al_2O_3$) is somewhat remarkable in that it is the only member of the lime alumina series showing pleochroism It seems probable that, in aluminous cement at least, this is not a pure compound and that ferrous and other oxides are also present

Many difficult problems still remain in the study of pozzolanas and of the physical structure of hydrated cements, but in connexion with the last of these there now appears to be a definite trend towards the view propounded by Le Chatelier that the hardening of Portland cement is primarily to be attributed to crystal formation

During the period of the meeting and the tour which preceded it, visitors were entertained with much generosity by their Swedish hosts, and they owe to them a debt of gratitude both for this and for their work in the organization of a very successful meeting

Hydro-Kinetic Power Transmitter[*]

By Prof F C. Lea

THE problem of devising a hydro-kinetic power transmitter capable of performing effectively the functions both of a clutch and of a change speed gear has not infrequently been declared to be incapable of solution Tests of a transmitter evolved by Commendatore Piero Salerni indicate that the problem has now been satisfactorily solved Within the range of variation of torque ratio requisite in an automobile or a heavy lorry the transmitter in question performs the two functions effectively and has an advantage over the orthodox clutch and gear mechanism in efficiency, performance, simplicity, soundness of construction, and also cost Furthermore, due to its inherent smoothness it relieves the whole of the transmission system, from engine to road wheels, of shock loads and thus reduces general maintenance

A variable ratio hydro-kinetic transmitter consists essentially of three vaned elements, namely, a centrifugal pump or driving element, a turbine or driven element, and a reaction element In the new transmitter the design of each of these elements involves important original conceptions, and of these conceptions that which relates to the centrifugal pump is of a fundamental nature and has important implications

In a hydro-kinetic power transmitter which has to function under conditions varying as widely and unpredictably as in an automobile or a locomotive, the major causes of loss of energy have heretofore been (1) unsteadiness of motion of the liquid medium within the ducts constituting the hydraulic circuit of the transmitter, (2) shock at the inlet of the driven element Of these two causes of inefficiency, the first, although *per se* the lesser, is fundamental, since the second, though considerably graver, is in consequence of the first

Since the liquid medium has to pass from a vaned driving element to a vaned driven element rotating relatively to one another at greatly differing and constantly varying speed, it is evident that, if losses of prohibitive magnitude are to be avoided, the rotational velocity with which the liquid emerges from the driving element must be so controlled that the direction in which the liquid impinges upon the receiving ends of the vanes of the driven element is maintained under all conditions, at an angle at which the liquid can be received without appreciable shock Hitherto such control has not been achieved Control of velocity variations implies, as a pre-requisite, steadiness of motion of the liquid, and it was held that in a centrifugal pump—and therefore in a hydro-kinetic power transmitter—the motion of the liquid could not be other than unsteady Hence the accepted theory that under variable conditions a hydro-kinetic power transmitter can function with acceptable efficiency only within a comparatively narrow range of variation, and that efficient performance by a single transmitter of the widely differing functions of a clutch and of a variable ratio gear is an impossibility

The fundamental characteristic of the new transmitter is that its driving element is a centrifugal pump of such a construction that the motion of the liquid within its ducts remains steady for the velocities that obtain in the ducts, with the result that a steady stream can be maintained within the hydraulic circuit of the transmitter under all conditions, and velocity variations can be, and are, adequately controlled By virtue of this characteristic, both the fundamental and the consequential causes of loss of energy are virtually eliminated

A series of laboratory tests have been carried out directed towards establishing the soundness of the hydraulic principle which governs the design and functioning of the machine, and I have had opportunities of observing and testing the performance of it in an automobile The automobile tested was a standard 21 6 h p 1936 model fitted with the standard size tyres and the standard back axle ratio of 4 1 to 1, the unladen weight of the vehicle being 29 cwt The tests included trials under all driving conditions, that is, in traffic, in hilly country and on the open road

---

[*] Substance of a paper read before Section G (Engineering) of the British Association on August 22

The hill climbing capacity of the vehicle, and the rate of its acceleration at get away and under all other conditions, have proved to be appreciably greater than is advertised by the makers as achievable by the same model when driven with the standard clutch and gears , and, though acceleration was lively, it was always smooth and progressive, the torque ratio decreasing gradually as road speed increased Inasmuch as with the transmitter there is neither de clutching nor gear changing, optimum performance is achieved without involving gear changing skill on the driver s part Passage from drive at the ratio of 1 to 1 to drive at higher ratios and *vice versa* is controlled solely by the accelerator so that even at very low speed the car is driven at the ratio of 1 to 1 when acceleration is not needed while torque increase takes place whenever needed the moment the accelerator pedal is pressed hard

The hill climbing performance of the vehicle was particularly impressive A special hill climbing trial was made on the 1 in 4 portion of the Brooklands test hill The car was loaded with progressively greater weight until the final test when a net load of 22 cwt was put on the car The car was then driven on to the 1 in 4 portion of the hill was stopped and then restarted without difficulty on the same gradient and was driven comfortably to the top of the hill This particular feature should prove of great advantage in heavy lorries caterpillar tractors and the like

I have carried out also a prolonged road test to ascertain the fuel consumption of a car fitted with the transmitter as compared with the fuel consumption of the same model when fitted with the standard clutch and gear box mechanism This test has proved that with the transmitter a saving in fuel is effected

As a result of tests in the laboratory and on the road and of an examination of the working parts after they had been in use in an automobile over 65 000 miles I have come to the conclusion that

(1) The transmitter resolves in a satisfactory manner the problem of transmission of power at a torque ratio varying automatically and gradually within the whole range covered by the orthodox friction clutch and change speed gear mechanism

(2) Its application in an automobile in substitution for the orthodox clutch and gear mechanism results in an improvement of the performance of the vehicle in get away general acceleration, hill climbing drive in traffic and drive on the open road

(3) The mechanical construction of the transmitter is in every way simple and sound , as compared with the orthodox clutch and gear mechanism it is simpler and less costly and its overall efficiency (as measured by petrol consumption on a long run) is appreciably greater

(4) Its scope transcends the field of the automobile and should include vehicles of every kind driven by internal combustion engines both of the petrol and of the heavy oil type

Progress in Seismology

THE forty third report of the Committee of Seismological Investigations of the British Association has just appeared and shows great activity on the part of the members and others in numerous directions The six Milne Shaw seismographs belonging to the British Association have remained on loan to the seismological stations at Oxford (2), Edinburgh, Perth (Western Australia) and Cape Town (2) During the year a Jagger shock recorder has been made for the Committee at Bristol under the supervision of Dr C F Powell, and this instrument is to be set up at Dunira, near Comrie (the village in Perthshire which is famous for the prolonged series of minor earthquakes in the last century), thanks to the co operation of Messrs Macbeth and White At Kew Observatory, the three Galitzin and two Wood Anderson seismographs have been rehoused in a new underground building, and it is very satisfactory to learn that in their new position they are not affected by the wind as they were previously, due to the rocking of the building A full description of the new housing is being published in a memoir written by Dr A W Lee

It is very satisfactory to learn that the work on British earthquakes which was carried on so long and so assiduously by Dr C Davison is now being continued by Dr Dollar with the support of the Committee Dr Dollar is organizing the collection of data very thoroughly, and already has collected information from numerous collaborators concerning six earthquakes, four subsidences and mine shakes, two explosions and six earth tremors felt by people in Great Britain since July 1, 1937 The earthquakes had the following dates and epicentres 1937, July 9 at Walsall in Staffordshire 1937 July 20 in Perthshire 1937 September 8 at Horsham in Sussex , 1937 December 4 at Comrie in Perthshire 1938, March 21 in S E Edinburgh and 1938 June 11 with epicentre at Ghent in Belgium The latter was by far the most important though the only damage done in Great Britain appears to have been a single fall of a few tiles at Herne Bay, in Kent The low rumbling earth sound was imperceptible west of London In the West Indies earthquakes for the time being appear to be less frequent The Weichert seismograph and eight Jagger shock recorders are still in operation in the care of Mr Kelsick who is making regular reports From August until November 1937 about forty earthquakes were reported by observers in Dominica and valuable reports on the geological structure of the island and on the distribution of earthquake centres were written by Mr A G Macgregor and Dr C F Powell

The work of the International Seismological Summary is being actively pursued at Oxford by Mr J S Hughes and Miss E F Bellamy The I S S has now been prepared in manuscript as far as July 1933 and January, February and March are in the press From January 1933 onwards an attempt is being made to distinguish between anaseisms and kataseisms Theoretical work on southern earthquakes and the core waves periodicities and deep focus shocks has been done by the indefatigable Dr H Jeffreys, and on the travel times of *P* and *S* waves by Dr A W Lee Dr E C Bullard is likely to undertake work on the thickness of the strata overlying the continental shelf round the British Isles

Science News a Century Ago

A Record Balloon Ascent

ON the evening of September 11, 1838, Charles Green (1785–1870) the aeronaut, made The Second Experimental Ascent with the great Nassau balloon, accompanied by a Mr Rush In his account of the journey which he described fully in *The Times* of September 15, he said that the balloon and its appendages weighed 4056 lb of which the balloon, netting and car accounted for 702 lb the ballast for 1,500 lb, he and Rush 145 lb each, the grapnel 32 lb and the elastic rope to the latter 20 lb The remainder was due to the weights suspended from the car and released on starting The balloon was set free from the Vauxhall Gardens at 6 30 and landed near Lewes an hour and a quarter later The barometer used was made by Mr Jones, of Charing Cross ' The greatest altitude we reached was 27,146 ft, indicating an elevation from the earth of 5 miles and 746 ft the barometer having fallen from 30 50 to 11 and the thermometer from 61 to 5 or 27 degrees below the freezing point

Ure's "Dictionary of Arts and Manufactures"

IN 1838 Dr Andrew Ure (1778–1857), a Scottish chemist, published the first part of his Dictionary of Arts, Manufacture and Mines' In a notice of this, *The Times* of September 12, 1838, said This was a book much wanted The first number or part appears to be very well done, and contains a mass of information, important to the generality of readers, divested of the difficulties of technicality and the pedantry which generally confuses and deters the mere common sense and common capacity student The first part has some articles of very general interest—viz, Acetic Acid, Alcohol, Assay, Beer, etc ' Quoting from the article on ' Baths," in which reference was made to the water supply of London, the reviewer added the extract I am led to these remarks by observing the filthy state of the water usually supplied at very extravagant rates by the water companies It often partakes more of the *appearance of pea soup than of the pure element* and he who reflects upon the miscellaneous contents of Thames water, will not have his appetite sharpened by a draught of the Grand Junction beverage nor feel reanimated and refreshed by bathing in a compound so heterogeneous and unsavoury '

Loudon's "Arboretum et Fruticetum Britannicum"

ON September 15, 1838, the *Athenæum* reviewed the Arboretum et Fruticetum Britannicum, or the Trees and Shrubs of Britain, Pictorically and Botanically delineated, etc, with their Propagation, Culture, Management, etc "The English gardener,' the journal said, is the best in Europe, the English forester the worst nowhere has art more generally neglected the advantages of a favourable climate than in English woods

"Mr Loudon s object has been to enable the landed proprietor to avail himself of the discoveries of modern science, and to show him the real value of the many new species and varieties of trees and shrubs now in this country He has performed his task with great industry and perseverance, the results of which are eight octavo volumes, containing 2,694 pages of closely printed letterpress, 297 figures of plants and 2,546 woodcuts The appearance of the plants themselves, the value of their timber, the kind of soil they require, the manner of multiplying them, their periods of flowering and bearing fruit, the climate most favourable to their growth, their botanical distinctions are all discussed in ample detail So useful a book upon trees and shrubs is not to be found in any language

John Claudius Loudon was born in Lanarkshire in 1783 and died in Bayswater in 1843 He was brought up as a landscape gardener, and between 1813 and 1828 made many visits to the Continent In the writing of his later works he was assisted by his wife Jane Loudon (1800 58)

Forthcoming Events

Fifth International Congress for Applied Mechanics, September 12–16, at the Massachusetts Institute of Technology, under the presidency of Prof K T Compton

Faraday Society September 15–17 —General Discussion on Luminescence, in the Biochemical Laboratory, University of Oxford

Appointments Vacant

Applications are invited for the following appointments on or before the dates mentioned

A Senior Professional Officer (Physiology) and a **Senior Professional Officer (Biochemistry)** in the Department of Agriculture and Forestry in the Union of South Africa—The Secretary High Commissioner for South Africa South Africa House Trafalgar Square London (Application form 7 83 September 12)

Keeper with knowledge of archæology in the National Museum of Antiquities of Scotland—The Secretary Board of Trustees Portrait Gallery Buildings Edinburgh 2 (September 17)

Lecturer in the Department of Pharmacy and Biology at the Central Technical College Suffolk Street Birmingham 1—The Principal (September 20)

Principal of the Bengal Engineering College Sibpur near Calcutta—The High Commissioner for India General Department India House Aldwych London W C 2 (September 23)

Assistant III (adult male) on the staff for scientific research of the War Department—The Superintendent Air Defence Experimental Establishment Biggin Hill Kent (postcard September 23)

An Assistant Lecturer in Biology and a **Lecturer in Physics** in the University of Western Australia—The Agent General for Western Australia Savoy House 115 Strand London W C 2 (October 1)

A Lecturer in Physics and a **Professor of Philosophy** in the University of Queensland—The Agent General for Queensland London, or Universities Bureau London for conditions of appointment (Registrar of the University of Queensland October 1 and 15 respectively)

Three European Engineer Sub Lieutenants in the Royal Indian Navy—The Secretary Military Department India Office London S W 1 (October 15)

Senior Research Assistant in Highway Engineering in the University of the Witwatersrand *Johannesburg*—The Secretary High Commissioner for South Africa South Africa House Trafalgar Square London W C 2 (October 17)

Professor of Anatomy in the University of Birmingham—The Secretary (October 31)

Lecturer in Forestry in the University of Aberdeen—The Secretary (October 31)

Chemical Assistant in the laboratory of the Colne Valley Water Company Aldenham Road Watford Herts—Chief Chemist (endorsed Chemical Assistant")

The Science Museum, South Kensington

THE rapid extension of scientific knowledge and of its application to industry during the past fifty years and most particularly in the post War period has exercised a tremendous influence on our social and economic life We are not yet able to utilize and control this to full advantage and therefore its source and development require to be revealed in as comprehensive and comprehensible a manner as possible to those who seek to understand The Science Museum at South Kensington aims to provide a proper representation commensurate with its importance of the scientific and technical aspects of human endeavour and achievement in the national life by means of exhibits which provide a continuous story from the birth of a new idea expressed in a new material instrument or machine up to its most modern development It differs from other national museums in that it deals with an aspect of life which is essentially dynamic and rapidly progressive and its task necessarily becomes an increasingly complex one

The continuous growth of scientific knowledge and the progressive reduction in the time lag between its discovery its application in industry and its transformation into goods and services available to the public present a formidable problem to those responsible for recording the process of historical evolution This is particularly the case since many modern industrial developments have arisen not so much from an independent expansion of one branch as from the interaction of several branches of scientific knowledge so that sectionalization in presentation is rendered increasingly difficult

The object of the Museum is in the first place educational It is inevitable that the community will become increasingly aware of the reaction of science on its everyday life and a well equipped museum is the best means of ensuring an intelligent appreciation of scientific and technical developments and of the benefits which they bestow It is very important that the Science Museum should keep abreast of these developments so that the average visitor may see clearly the relation to what has gone before of the devices which he is called upon to use in his normal activities In performing this function the Museum does a very great service to the industry of the country

In order to deal with this complex situation the Science Museum has adopted the practice of combining with its permanent historical and sectionalized exhibition exhibitions of a temporary character dealing with special industrial developments of considerable present importance from which individual exhibits may be withdrawn afterwards for incorporation in the permanent collection The interest which these temporary exhibitions arouse may be judged from the fact that the most recent one on Electrical Illumination was attended by more than a quarter of a million people while during 1937 the total number of visitors to the Museum as a whole was more than one and a quarter millions The vast majority of these are not idle sightseers but persons genuinely interested and keen to learn something from what they see and it would be impossible to over estimate the educational and inspirational benefit which accrues particularly to young people from this visual exposition of scientific and technical development

It has become increasingly evident however that the space available is quite inadequate to enable the Museum to develop in a manner befitting its importance At the present time the existing collection is badly overcrowded and it is not possible to house or display it with the dignity which has been given to our arts and humanities to find accommodation for objects in store or acquirable which should rightly be exhibited or to advance towards the creation of several new sections for which there is a pressing need

In 1911 12 a Committee under the chairmanship of Sir Hugh Bell recommended the construction of new eastern and central portions and visualized their completion by 1922 the eastern portion was finally completed in 1928 but no start has yet been made on the centre portion Even however if the latter were available in the form suggested by the Committee the total space then available would permit of only a partial satisfaction of the present needs and would therefore leave no provision for such natural growth as is to be expected during the next fifty years The total exhibition space which the Advisory Council of the Museum has estimated to be necessary amounts to some fifty per cent increase over that envisaged by the Bell Committee It is realized that this estimate is conservative but it has been kept down to this figure deliberately in order that the collections in the Museum should not exceed what can be usefully displayed in the convenient compass of one building The Council advocates that the main exhibition galleries should be confined to not more than three floors a system which has been wisely adopted in both the older and the newer museums of Great Britain and other countries

These considerations constitute the basis of recommendations which have been put before the Board of Education recently by the Advisory Council and with the full support of the Federation of British Industries for a considerable extension of the present space allocation in South Kensington The present time is opportune since the site adjacent to the existing buildings on which any extension must necessarily occur if decentralization is to be avoided may soon become available by the project now under consideration for the readjustment and expansion of the Government and collegiate institutions situated on the area between Kensington Gore and Cromwell Road The calculation of the site area necessary to provide the estimated floor space required and allowing for the inclusion of some central courts to admit light into the galleries covers the area enclosed by the Natural History Museum boundary Exhibition and Imperial Institute Roads and Queen s Gate exclusive of the two blocks occupied by private residences and the Meteorological and Post Offices The acquisition of this site is in the opinion of the Advisory Council essential if practical effect is to be given to that long view of the future function and progress of the Museum which its national importance and value to the industry demand

It is to be hoped therefore that the Board of Education will give the most serious consideration and its ultimate endorsement to these recommendations the value of the Museum as a means of educating the general public and of demonstrating the continuous development of our national resources is becoming increasingly appreciated by industry and there need be no doubt as to the enthusiasm with which industry would support and give assistance towards their full subsequent realization

The example has been set in Germany by the Deutsches Museum in Munich and in the United States by the Rosenwald Museum in Chicago in Great Britain we need not and should not suffer as we now do in comparison with them

Kinetic Theory of Gases

Kinetic Theory of Gases
with an Introduction to Statistical Mechanics By Prof Earle H Kennard (International Series in Physics) Pp xiii + 483 (New York and London McGraw Hill Book Co Inc 1938) 30s

NEW books on the kinetic theory of gases are rather rare phenomena The best early comprehensive works on the subject were written in German by O E Meyer (Kinetische Theorie der Gase first ed 1877) and L Boltzmann (Vorlesungen über Gastheorie vol 1 1895 vol 2 1898) the former book was meant for physicists and the latter for mathematicians The second edition of Meyer s treatise translated into English by R E Baynes was published in 1899 and even now is worth reading It has not been reprinted probably because of the appearance in 1904 of the first edition of Sir James Jeans s Dynamical Theory of Gases

The expressed aim in Jeans s first edition was to develop the Theory of Gases upon as exact a mathematical basis as possible The fact that further editions of this book were called for in 1916 1921 and 1925 shows that the book proved widely useful and acceptable In the second and later editions the original aim was combined with an attempt to make as much of the book as possible intelligible to the non mathematical reader for which reason the plan of dividing the book to a large extent into mathematical and physical chapters which was already partly adopted in the first edition was more extensively followed The later editions grew in size but not because the developments of the classical Maxwell Boltzmann theory made between 1910 and 1917 were incorporated only their results were quoted Little was added moreover concerning the new experimental researches on gases the new matter mainly referred to the quantum theory which gave an entirely new outlook on the difficulties concerned with the equipartition of energy discussed at length in the first edition Much of the chapters on quantum theory in the later editions had but slight bearing on gas theory

In 1927 L B Loeb published the first edition of his Kinetic Theory of Gases which made a considerable break with the Jeans tradition He omitted altogether most of the difficult mathematics for which he substituted an account of many topics nearly or wholly omitted by Jeans such as the experimental and theoretical work on the Brownian motion by Perrin and Einstein the studies of rarefied gases by Knudsen and a discussion of magnetism in gases

Now again from across the Atlantic comes another Kinetic Theory of Gases in English by E H Kennard This resembles the book by Loeb much more than that by Jeans The treatment is actually more mathematical than that of Loeb but the difference between the two is small compared with the great gulf that would separate either book from one giving a systematic mathematical presentation of the pure kinetic theory of gases Few physicists however will wish to penetrate far into the mathematical labyrinth of the theory of gases

Justification for a new book on the subject on the same general lines as were followed by Loeb may be found in Prof Kennard s inclusion of work both experimental and theoretical that has appeared since 1927 Among the additional topics or topics treated in a materially different way in Kennard s book are statistical mechanics leading up to statistical wave mechanics the wave mechanics of gases and molecular beams and scattering The author also goes further into the approximate theory of the mean free path phenomena and follows Jeans—somewhat distantly in referring to terrestrial and planetary atmospheres

If one book could be made out of the two by Loeb and Kennard the reader s convenience might be still better met than by the possession of the two separate works But it will certainly be worth the while of many possessors of Loeb s treatise also to read the new book by Prof Kennard The book is well documented and will materially help readers wishing to follow recent work although the kinetic theory is now as Prof Kennard says in a state of staid maturity it retains importance in modern physics which has many interesting interactions with it an example is the theoretical calculation of the accommodation coefficient duly referred to in the book under review A novel and commendable feature is the inclusion of a number of exercises for practice

---

Petrography of the Igneous Rocks

A Descriptive Petrography of the Igneous Rocks By Prof Albert Johannsen Vol 3 The Intermediate Rocks Pp xiv+360 Vol 4 Part 1 The Feldspathoid Rocks Part 2 The Peridotites and Perknites Pp xvii+523+1 plate (Chicago University of Chicago Press London Cambridge University Press 1937) 21s net each

VOLUMES 3 and 4 of this work complete what must be the most compendious handbook of petrography ever issued In the first volume Johannsen gave an admirably illustrated account of rock textures and structures, together with an account of the many systems of classification in use He himself has devised a quantitative mineral classification and this is used in the descriptive part of the work In this system rocks are first divided into classes according to the relative amounts of light and dark coloured minerals present and then into families and sub families on the percentage ratios of certain other mineral components actually present

To some extent the divisions thus made cut across those generally used Thus the second volume includes all the rocks with more than 5 per cent of modal quartz and quartz bearing varieties of basic rocks are found in the same volume as the acid granites and rhyolites. Those with less than 5 per cent are described in the third volume under the title of "The Intermediate Rocks". They comprise syenites, monzonites, diorites, norites and gabbros together with their hypabyssal and volcanic equivalents. In the older classifications many of these are termed basic, and indeed such rocks, norites, gabbros, dolerites and basalts, occupy half the volume. Volume 4 is divided into two parts. The first part, "The Feldspathoid Rocks", includes the so-called alkali-syenites, essexites and gabbros with the corresponding lavas and intrusives. In the second part, "The Peridotites and Perknites", the ultrabasic rocks, are described.

One of the author's aims is to bring precision to the nomenclature and classification of igneous rocks. Accordingly, in his treatment of the families, the units for descriptive treatment, he first reviews the history and definition of the rock name. He is able to show that with the passage of time many rocks have been given names to which they are not entitled, and that many new names have been given to rocks that would conveniently fall into types already defined. Where ambiguity occurs he suggests a re-definition of the type, or in some cases that the name should be abandoned and another adopted. He is fertile in the invention of new names. He then proceeds with the macro- and micro-scopic characters of the rocks in the family, and in all the principal groups gives a full account of the mineralogy. Tables of chemical analyses, of norms and of modes are abundant. In the author's classification the mode is all-important, and where the original description of a rock lacks this, Johannsen has frequently supplied it from typical material. The treatment is very full and comprehensive.

Some idea of the scope of the work is given by the indexes, of which three are given at the end of the last volume. More than 800 authors are cited, some of them being referred to many times. Localities number more than 2,000, and there are more than 1,200 rock names. Though many of these have been devised by Johannsen to suit his classification, there can be few, if any, old names omitted. These are all adequately referenced, and it is pleasing to note that the author has personally verified all references to which he has access. The few that he has been unable to check are indicated.

The value of the work is independent of the classification or the nomenclature. An enormous amount of data, gathered from world-wide and often relatively inaccessible sources, is made available in one work. To petrographers it will be a mine of information and a great time-saver. It is the fruition of the life-work of a great petrographer and scholar.

The general get-up of the volumes is excellent. They are well printed on good paper, with pleasing type. Proof reading has been well done, the few corrigenda for the early volumes being mainly in the spelling of place-names. The binding is such that a volume of 500 pages will remain open at any page. The book will be a welcome addition to any geological library.

Astrophysical Methods and Problems

Astrophysik

Herausgegeben von B. Stromgren. (Handbuch der Experimentalphysik, herausgegeben von W. Wien und F. Harms, Band 26.) Pp. xv + 998. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1937.) 76 gold marks.

AS the authors point out, the vital point in a presentation of astrophysics in one volume, such as offered here, is the limitation of the material dealt with. In accordance with the character of the "Handbuch der Experimentalphysik", of which it forms volume 26, in planning this volume the methodology of the observing astrophysicists has been brought to the fore. Therefore, the main emphasis is given to a very complete representation of the methods and instruments of astrospectroscopy and astrophotometry. To perform this task it was necessary, of course, also to look into the problems of theoretical astrophysics, in order to elucidate the purpose and value of the multitude of spectroscopic and photometric observations which are now available.

In emphasizing this, Prof. Strömgren points out very clearly his and his collaborators' aims. The book is intended for both the physicist and the astronomer. It furnishes the former with the latest information regarding the methods of astrophysics. The general principles of astronomical spectroscopy and photometry are the same as those used in the laboratory. But, to solve the special astrophysical problems, a number of quite independent methods of interest to the physicist have been developed, and the methods of laboratory physics have been refined.

For the astronomer the book is intended to serve as a textbook and a handbook of practical astrophysics ’ This is a great promise for a one volume work on a subject of such wide scope not hitherto treated in one volume as a homogeneous whole But the promise is kept and it is difficult to avoid superlatives in referring to the work

The introductory chapter by J Stobbe of the Kiel Observatory gives in 178 pages an outline of those astronomical subjects which do not find a place elsewhere in the book Here we have paragraphs on co ordinates and time on the positions and motions and radiation of the stars giving the essential principles Stobbe goes on to give an exposition of the theoretical foundations of photometry and spectroscopy adding a description of the optics and mechanics involved in the construction of astronomical instruments and observatories An instructive chapter on the physiological and psychological components of the observer s activity concludes this clearly written and well condensed summary the value of which is enhanced by ample references

The following 139 pages cover spectral analysis so far as it is concerned with qualitative con siderations In this chapter W Schaub first outlines briefly the problems involved in the classification of the stellar spectra and refers to spectroscopic parallaxes radial velocities rotation of the stars etc But the position of greatest importance is occupied by an excellent description of the instruments in use namely the different types of spectrographs measuring microscopes and spectrocomparators and a full account of the methods for measuring and reducing the spectro grams Here we find also especially useful the detailed survey of the ways of testing the optical and mechanical parts of the spectrographs and of all the various corrections to be allowed for in practical radial velocity work

The photometric part of the work is naturally the most extensive of all its treatment being divided up between B Stromgren (Copenhagen and Chicago) H Kienle (Gottingen) and J Hellerich (Hamburg) Stromgren s two chapters —one on the tasks and problems of astrophoto metry, the other on objective photometrical methods —362 pages in all form more than one third of the whole contents of the book Not only in quantity but also in quality these chapters form the key of the whole and unite in an article of unique construction a wealth of material hitherto scattered in countless sources

The wide variety of problems and the limita tions of astrophotometric measures are elucidated in great detail Comprehensive sub chapters deal with the present photometric systems and catalogues, with the results of the work on colour indexes and on other colour equivalents A full and stimulating discussion is devoted to the problems of spectrophotometry towards which so much of the present day interest in astrophysics is directed Here Stromgren shows how the con tinuous spectrum has recently been opened up to far reaching quantitative investigations and how the resulting different types of temperatures etc are related to each other Then he proceeds to the measurement and reduction of line contours and finally treats with a number of special problems such as the spectrophotometry of surfaces of the sun of galactic nebulæ etc Atmospheric extinc tion belongs also to Stromgren s subject and is disposed of in a short but interesting manner whilst a full account is given of the instruments used for the measurement of the total radiation of sun planets stars such as pyrheliometers bolometers thermo photo electric and selenium cells

Photographic photometry is dealt with in a masterly way by H Kienle The well known ability of this author for clear concentrated and vivid writing helps greatly to make this chapter not only a most important but also a very pleasant one The widely scattered data on the properties and the treatment of photographic plates are to be found here critically summarized and the reader finds references to appropriate literature The same may be said of the discussion of all the many different types of photometers designed for measuring photographic effects Thus Kienle s 145 pages give invaluable information to the astrophysicist in a field of ever growing interest

It is logical and useful that two shorter chapters of 114 pages have been separated from Stromgren s and Kienle s work namely the treatment of the methods and the results of visual photometry and of colour measurement with colorimeters effective wave lengths etc Both articles have rightly been entrusted to J Hellerich of the Hamburg Bergedorf Observatory whose own successful work lies in this line thus enabling him to give an authoritative and well written survey

The same remark applies indeed to the whole book A very restricted number of well chosen representatives in their own special fields have succeeded in avoiding the weaknesses of some similar undertakings in other branches of science where too great a number of collaborators pre vented the necessary co ordination thus leading to unnecessary repetitions or omissions and to discord in style and presentation But in the new Astrophysik Rosenberg’s thoughtful plan ning and Strömgren s firm direction have created a book which will impress the reader as being a first class standard work

A B

A Manual of Psychological Experiments

By Edwin Garrigues Boring, Herbert Sidney Langfeld, Harry Porter Weld, and collaborators Pp ix+198+3 plates (New York John Wiley and Sons, Inc London Chapman and Hall Ltd , 1937) 8*s* 6*d* net

THIS is an elementary manual of psychological experiments suitable for first year students and containing about sixty experiments mostly new Besides the editors, seventeen other psychologists have collaborated to produce the book The work is designed apparently to accompany the widely used general text book in psychology by the same authors, but it can also be used together with any good text book

Many of the fifty nine experiments are planned on traditional lines , twenty three are concerned with psychophysics and sensation, seven are on perception, eight on learning and the rest on emotion, action thought and personality The methodology of each experiment is given briefly and clearly together with a number of questions and a few essential references

An advantage of the course of experiments is the simple and inexpensive apparatus that is required A disadvantage is the absence of the more recent experiments used in researches in *Gestalt* psychology There is only one experiment on memory and none on attention, will imagination, perseveration, oscillation or fatigue It is a relief to see that the plethysmograph is not introduced as a measure of affectivity Most of the experiments are planned to take about one hour , a few take about two hours and can be performed with large or small groups

A short chapter is included on the computation of a few statistics, but no instruction is given in the psychophysical methods

The manual is to be recommended for use by students in England, and could also be used to much advantage in tutorial and extension classes in psychology J I COHEN

A Textbook of General Botany

for Colleges and Universities By Richard M Holman and Prof Wilfred W Robbins Fourth edition Pp xvii+664 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1938) 20*s* net

THE subject matter in the fourth edition of this familiar text book has not been materially changed, though in the light of most recent research it has been brought up to date It is a pity that the subject-matter has not been modified for it is based essentially on the morphological concept Physiology receives scant treatment the chapter on evolution and heredity is wellnigh out of date and genetics is practically ignored Research on the more practical side of botany, and especially strictly economic botany, is going on apace, especially in the country of origin of this book, yet it scarcely receives a mention

These blemishes are unfortunate, for works by the late Prof Holman and Prof Robbins are well known and widely used The book, as it is, brings that narrow conception of botanical science to the reader which was peculiar to the academic student of twenty years ago Substantial changes are slowly taking place, and it is to be regretted that such an otherwise authoritative and well written text gives so little attention to them

The Farming Year

By Prof J A Scott Watson Pp 144+64 plates (London, New York and Toronto Longmans, Green and Co , Ltd , 1938) 7*s* 6*d* net

THIS excellent little book has been written at the request of the National Federation of Young Farmers Clubs The farmer s son may be familiar with the type of farming practised in his district but in most cases he will not have had the opportunity of taking at first hand a general view of our very varied husbandry The next best thing is to have the situation briefly and accurately set out by a competent observer Prof Scott Watson has written his account in very simple style, and continually directs the attention of his readers to the causes that have operated to mould agriculture into its present form The main styles of farming each form the subject of a chapter, and the scope is wide enough to include vegetables and flowers farming under glass and fruit An outstanding feature of the book is the quality of the numerous illustrations, which with their well phrased captions are full of information

Readers other than young farmers will be found for this book For the townsman young or otherwise it will provide a very readable account of an industry that makes as big a demand as any on the technical skill and business ability of its members

A Swahili Dictionary of Plant Names

By P J Greenway Pp xvi+112 (Dar es Salaam Government Printer 1937) 3*s*

MR GREENWAY has performed a very valuable service to all interested in the life of the East African native by the preparation of this dictionary Hitherto the available information was scattered through larger dictionaries or recorded only in botanical papers or on herbarium sheets Now the accurate identification of the native names of medicinal, food and other plants will be greatly simplified

Under each native name the English equivalent, if any, is given, followed by a brief description and the scientific name and family Notes on the uses of the various species are also given, and there is a list of native morphological terms and a botanical glossary

As Mr Greenway remarks in his introduction, the vegetable kingdom plays a very important part in the economy of the African native A thorough knowledge of native usage in plant nomenclature is therefore a valuable asset in understanding the African mentality, and the publication of this well-prepared and handy dictionary will be welcomed by all those concerned with study and administration in East Africa

Radio Transmission and Solar Activity*

By Prof E V Appleton, F R S.

I PROPOSE to review very briefly the progress made in certain branches of radio research since the last General Assembly of the International Scientific Radio Union in 1934 In selecting such topics for consideration I have been constantly struck as many others doubtless have been by the way in which the range of the interests of the radio worker has been gradually expanding so that now it overlaps almost every field of physical knowledge In that everyday tool we employ the amplifying valve we find problems of thermionics electrostatics and electrodynamics The study of aerials and their radiative properties involves problems entirely analogous to those of physical optics The investigation of the travel of radio waves excites our interest in fundamental atomic processes by way of which the electron population in the ionosphere increases and decreases The profound control maintained by the sun on the ionosphere and especially the response of upper atmospheric conditions to events on the sun s surface identifies our interests closely with those of the solar physicist while by way of the troposphere which is the seat of atmospheric disturbances we find much of common concern with the meteorologist

Radio researches depend fundamentally on the behaviour of the electrical circuits we employ at both sending and receiving stations To make measurements on long waves and on low frequency oscillations is comparatively easy but with ultra high frequency oscillations where the wave length is comparable with the size of the apparatus such measurements have demanded the development of a new technique of great elegance in which our Italian colleagues have played an outstanding part The result is that with the availability of new valves and new circuits a rich field of research has been opened for our exploration

The study of the travel of ultra short waves to distances beyond the horizon has again directed attention to the classical problem of the transmission of waves around an imperfectly conducting earth The pioneer work of G N Watson on this subject has been used as the starting point of more recent investigations, but while the solution of the problem reached by him was formally complete its application to practical cases has encountered considerable practical difficulties Elucidations and extensions of Watson s analysis have been recently made by Eckersley Wwedensky and van der Pol and Bremmer which readily permit the comparison of theory with experiment in practical cases where the sender and receiver are elevated above the ground As the last two authors have shown the theory predicts no marked diminution in the intensity of television signals on wave lengths of the order of 7 metres when the receiver passes beyond the optical horizon of the sender The attenuation of such signals is in fact determined by the finite conductivity of the earth rather than by lack of bending over moderate distances Whether atmospheric refraction further assists the influence of the diffraction is still not quite certain and further systematic experimental investigations on the subject are desirable

The systematic investigation of the ionosphere by means of radio waves has been actively pursued during the last four years The critical frequency method of measuring such upper atmosphere ionization densities has now received widespread adoption and the register compiled by the Ionosphere Sub Commission shows that as many as twenty four stations are at present making measurements of this type in different parts of the world Observations have for example been made within ten degrees of the North Pole and within forty seven degrees of the South Pole In some cases both sender and receiver are manually operated in others part or all of the apparatus is automatic and requires merely maintenance attention But in all cases there is obtained the relation between equivalent height of reflection at vertical incidence and electric wave frequency from the features of which the maximum electron concentrations in the various ionospheric regions may be calculated

Observations made by the critical frequency method are now sufficiently extensive to permit us to make various deductions concerning the major ionospheric variations There is now ample evidence to show that during the daytime the behaviour of Regions E and F_1 is such as can be explained by a simple theory involving the simultaneous operation of photo ionization by solar radiation and recombination Region F_2 on the other hand behaves abnormally since experiments conducted in the northern hemisphere have shown that over a period of years the summer noon ionization is actually less than the corresponding winter value Valuable additional information on this point has more recently resulted from the comparison of results made at the two stations of Washington and Watheroo which are situated at approximately the same distances north and south of the equator At first it appeared that Region F_2 ionization varied similarly at both of these stations indicating an annual effect but a more extended series of observations showed that this was not the case The nature of the anomaly was clearly elucidated by Goodall who in a very important discussion of the available Washington and Watheroo data showed that there is a seasonal variation in both hemispheres together with non cyclic changes which appear to affect both hemispheres similarly and is related in some way to the general solar activity It will be thus seen that there are two problems associated with Region F_2 One is to explain the anomalous seasonal effect first recognized in the northern hemisphere and the other is to explain the non seasonal variation which has been found in the examination of the valuable observations in both hemispheres made by Berkner and his colleagues under the auspices of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington

---

* From the presidential address to the International Scientific Radio Union delivered in Venice on September 4

Advantage has been taken by members of the International Scientific Radio Union to make ionospheric observations on the occasion of three out of the four solar eclipses which have taken place since 1934 The results have amply confirmed the earlier conclusions that the electrons in Regions *E* and F_1 are liberated by solar photons and are captured according to a recombination law On the occasion of the total eclipse in Japan in 1936 an opportunity also arose to investigate the origin of the so called abnormal or sporadic Region *E* echoes which appear to be due to locally ionized clouds or strata embedded within the normal Region *E* From the results obtained there is a suggestion of a partial solar photon origin but it would perhaps be wiser to regard this more as an incentive to further work on the subject than as a definite conclusion The extensive results for the same eclipse have unfortunately not solved the vexed question of the origin of Region F_2 for while some observers interpret the data as indicating ionization by photons others argue equally plausibly in favour of ionization by corpuscles There is evidently need for a further critical examination of the available data in the light of the known abnormal behaviour of Region F_2 as well as for the harvesting of further experimental observations The forthcoming solar eclipse of October 1 1940 in South Africa and South America should provide us with an excellent opportunity for the latter The preparatory calculations concerning both optical and corpuscular eclipses in the ionosphere for this occasion have already been made by H M Nautical Almanac Office Great Britain

I now turn to a fascinating story in the history of solar physics the first chapter of which was written many years ago On September 1 1859 a historic observation was made by R C Carrington a British astronomer While making in the forenoon of that day his customary examination of the forms and positions of spots on the sun he was startled to note two patches of intensely bright and white light associated with a particular group He hastily left his apparatus to call some one else to witness the phenomena with him but on returning within sixty seconds was to use his own words mortified to find that the outburst was already much changed and enfeebled On calling at Kew Observatory a day or two afterwards Carrington was interested to learn that at the very moment he had seen the solar flare the three magnetic elements at Kew were similarly disturbed About 17½ hours after these disturbances there occurred one of the most violent magnetic storms ever observed It should be here noted that the year 1859 was one of sunspot maximum

This interesting story has acquired fresh significance in recent years as a result of the fertile collaboration of many workers on the subject of solar and terrestrial relationships In 1930 Mögel in an undeservedly neglected paper analysed a series of short wave radio observations made during the years of sunspot maximum 1927 29 In this paper he describes the occurrence of what he calls short disturbances or interruptions of radio communication over circuits traversing the illuminated side of the earth Such short disturbances were found to affect communication for periods up to an hour and were accompanied by a characteristic disturbance of the earth s magnetic field Mogel suggested that the radio and magnetic effects were due to abnormal ionization in the lower layers of the atmosphere

It would of course scarcely be permissible to deduce from the single observation of Carrington and the work of Mögel that the three phenomena solar flare radio fade out and characteristic magnetic disturbance were associated That connexion has been satisfactorily established only as the result of the combined efforts of many observatories and radio stations Such collaboration was prompted first by the French National Committee of the International Union which through its chairman M Jouaust directed the attention of other national committees to the reappearance of Mögel s short-disturbances in 1935 From that year onwards an extensive research has been conducted by numerous organizations and individuals At the request of Dr J H Dellinger for example special solar observations were made at Mount Wilson Observatory at times when fade outs were expected to see if any visible solar effect could be associated with them while an examination of old spectroheliograms immediately revealed the fact that a number of fade outs already recorded had been accompanied by bright chromospheric eruptions But perhaps the first really striking example of these inter related phenomena occurred on April 8 1936 when a very intense solar flare photographed at Mount Wilson was found to occur simultaneously with a widespread radio fade out and the characteristic magnetic variation As the solar activity has increased in recent years many more examples of such correlations have been noticed

To the student of the ionosphere the temporary abnormal absorption of radio waves during a fade out is a phenomenon of great interest When the disturbance is not too severe and weak echoes can still be received it is generally found that the height of reflection is not materially altered The fade out must thus be due as Mogel suggested to increased ionization at levels below those normally responsible for the reflection of medium and short radio waves Such increased electron content in what was identified many years ago as Region *D* would be expected to have three effects It would temporarily increase the conductivity of the lower ionosphere for the overhead currents which cause the daily magnetic variations and so account for the observed magnetic disturbance It would increase the normal Region *D* attenuation of radio waves passing through it and so explain the occurrence of the short and medium wave fade out At the same time however it would increase the reflection coefficient of Region *D* for the very long waves which are deviated by its lower boundary Such enhanced reflection of very long waves on the occasion of a short wave fade out was first noted by R Bureau in his study of the propagational characteristics of atmospherics

There can be little doubt that the enhanced ionization in Region *D* during a solar flare is electronic in character and that the exaggerated attenuating properties of this region as a radio transmission medium is due to the high frequency with which the electrons collide with the neutral molecules Since the attenuating stratum is produced at a low level the atmospheric absorption coefficient of the solar photons responsible must be relatively high Possibly the electrons in question are liberated by photo detachment from the negative ions which we suspect are present in large numbers during the daytime in Region *D*

Archæological Sequence in North-West Honduras

DURING 1936 a joint archæological expedition of the Smithsonian Institution and Harvard University excavated a number of sites in the Departments of Cortes Yoro and Santa Barbara in north west Honduras The expedition which was in the nature of an archæological reconnaissance rather than a systematic exploration had as its objective in part the extension of the exploratory work carried out by Dr W D Strong in north eastern Honduras on behalf of the Smithsonian Institution in 1933 in part and more immediately to carry further the work of Byron D Gordon (1895–97) and of the late Mrs Dorothy H Popenoe (1928–29) Mrs Popenoe s pioneer work at Playa de los Muertos where Gordon also excavated in affording valuable and much needed evidence of the stratigraphical relations of early cultures in this region had opened up new vistas in the study of the archæology of Honduras This evidence it was the purpose of the expedition to test and extend

A detailed report of the results of the excavations of 1936 is in course of preparation, but as the mass of material precludes early publication, a preliminary report has been prepared by Dr Strong the senior member of the expedition and his colleagues in which an account is given of the major results emerging from the investigation *

The sites investigated lie in what may be termed the drainage area of the Ulua River (including the Chamelecon River which formerly drained into it) north eastward from Lake Yojoa The environmental conditions of this region belong to two types On one hand are the broad alluvial valleys of the lower Ulua and Comayagua Rivers with dense rain forests on the other hand are the elevated mountain valleys with clear flowing streams in which the rain forest is limited to the border of the stream or in the Lake Yojoa area of the lake while raised plateaux with oak and pine afford a background

The sites examined are distributed geographically in three groups the Chamelecon group, of which Naco is the most extensive the Ulua and Comayagua group of which Playa de los Muertos is the most important and for the early culture the type and the Lake Yojoa group This last includes only the northern shore of the lake where is situated the most southerly ancient Mayan settlement The reconnaissance thus covered the northern half of a natural transition area between the Pacific highland and the Atlantic lowland regions At this point occurs one of the easiest passages across the central American isthmus from Tehuantepec to Panama a factor of considerable archæological and historical importance

---

* Preliminary Report on the Smithsonian Institution Harvard University Archæological Expedition to North Western Honduras 1936 By William Duncan Strong, Alfred Kidder II, and A J Drexel Paul, Jr *Smithsonian Miscell. Collect* 97 1 1938 Pp 129 + 14 plates

Characteristically the sites are found either in the alluvium of the broad lower river valleys or on the banks of the streams of the elevated valleys Hence while in the latter mounds affording evidence of habitation sites sometimes with burials added are accessible to excavation in the alluvial valleys owing to the depth of the river silt the investigation was most readily carried out by the examination of cultural deposits in the steep river banks exposed by the action of water

At the time of the Spanish conquest it would appear from early documentary and linguistic evidence this part of Central America was occupied by Jicaque and Lenca speaking peoples but various Nahuatl speaking (Aztecan) pueblos existed along what would seem to have been trade routes extending into this region from southern Mexico and the Pipil (Nahuatl) territory in Salvador One such line of settlement crosses the Chamelecon near Naco and extends east to a short distance south of Trujillo West of the Ulua there were groups of Mayan people their influence also extending well into Lenca territory The region in fact was a contact area in which advanced Nahuatl and Mayan peoples impinged from the west upon less advanced peoples to the east whose linguistic affinities were with the south and ultimately centred possibly through the Chibchan stock in northern South America The archæological data now made available bear out this evidence of contact

The artefacts obtained were predominantly ceramic—monochrome and polychrome painted ware There was also a large number of pottery figurines in human and animal form some of which are whistles or had been attached to whistles Artefacts of other material are comparatively speaking rare Obsidian flakes are ubiquitous but nowhere in large numbers Knife blades one projectile point and a few small celts were found Stone polishers pestles of large size hammer stones and broken metates with a few beads of jade jadeite and other material occurred on various sites Stone statues much mutilated are found in the Lake Yojoa area where the sites are particularly rich in painted pottery and have been a prolific hunting ground for collectors One specimen only of metal was found a small fish hook of copper from Las Flores Bolsa in the Ulua area Charcoal with hearths or fire pits is found on the floors of habitation sites while burnt clay shows the impression of wattle and daub The evidence of the numerous animal bones in the early culture of Playa de los Muertos points to a hunting people Human skeletal remains from the numerous burials were in too bad a condition to provide much if any material of evidential value

The excavations revealed a striking general resemblance in the stratification and contents of the deposits Two distinct cultural horizons are separated by a period of sterility The upper cultural level marked by the occurrence of potsherds begins on the stratified sites other than mounds at a depth below the surface of usually from forty to eighty centimetres but sometimes more It is characterized by two distinct classes of pottery painted and a coarse domestic ware On the painted pottery the decorative designs are either conventionalized animal or human forms or geometric They are of various colours red black white purple and sometimes blue on a background or slip of white black orange buff or yellow This ware is polished some to a high degree In some instances incised ornament also appears On most if not all of the sites however the second class or domestic ware predominates This is normally a monochrome varying from a deep or brick red to grey or black but a considerable number of sherds show crude linear designs in brown deep red or black

The upper cultural level is superimposed on a sterile level of a sand and/or clay extending from approximately two to as much as four metres down On certain sites a cultural horizon appears below the sterile deposits It belongs to an earlier culture and at Playa de los Muertos comprises from the four to the six metre level The distinguishing feature of this culture is a form of pottery falling into a number of types or classes according to surface finish and decoration The ware is found both with slip and without and is mostly highly polished One class however is a painted ware black and red or red and buff and rarely a white slip with red lines Not only is this painted pottery rare but also it is highly variable and has an experimental appearance Certain finds suggest that Usulatan ware such as is found in Salvador the earliest painted pottery found in Central America , forms a part of this early cultural complex At Los Narranjos on Lake Yojoa occurs what is apparently an early form of the Playa de los Muertos early culture It shows a very primitive type of pottery but its chronological relations are not yet definitely established

The main significance of these results lies not so much in the character of the finds on individual sites, as in the light thrown as a whole on the cultural sequences and affinities of north western Honduras and ultimately as a contribution towards the solution of the archæological problem of Central America more especially in the matter of cultural and ethnic origins

In determining the sequence and chronological relation of the cultures revealed by the results of this archæological reconnaissance, a point of departure is afforded by the excavations at Naco on the Chamelecon River, an important native settlement, also occupied for long by the Spaniards Here in association with evidence of Late Nahuatl influence and a painted pottery culture were found two pieces of European pottery of which, if one may have been a later intrusion the other was probably contemporary with the early Spanish occupation

From this point the cultures determined may be arranged in a chronological sequence as follows First in the upper cultural level comes the Ulua Polychrome, comprising the domestic monochrome and two (or three) classes of painted ware of which one, showing conventionalized human and animal forms, both from the character of the decorative motifs and the form of the vessels, is undoubtedly of Mayan derivation and with this is the class, or classes, termed Bold Geometric and Bold Animalistic, the latter from Lake Yojoa in which certain animal forms appear but nevertheless to be associated closely with Bold Geometric In both the Mayoid and the Geometric and Animalistic classes there is evidence of a lower and an upper type, indicated by a development from a more naturalistic to a more highly conventionalized style in which animal forms found in early Geometric disappear The Mayoid pottery occurs in such quantity as to justify the inference that it is the product not merely of Mayan influence but also of an actual association of Mayan settlers with the makers of the Geometric and Animalistic classes each group pursuing its own tradition The Geometric of the Ulua River is attributed to the Jicaque the Animalistic of Lake Yojoa to the related Lenca

As connecting links between the Ulua Polychrome and the earlier culture of the lower level of Playa de los Muertos are placed tentatively the Ulua Bichrome from Santa Rita and the early painted ware, Playa de los Muertos Bichrome, between which there would appear to be some evidence of relation The occurrence of Usulatan ware in this level at Santa Rita is a link with Salvador while the painted ware of Playa de los Muertos is referred to early levels at Uaxactun The early Playa de los Muertos culture from the lower level on this site, which precedes the sterile deposits may itself be preceded by the apparently primitive Monochrome from Lake Yojoa—a point still to be determined

As regards the absolute chronology of this series of cultures it is suggested not without reason, that the Ulua Polychrome represents a development which took place after the fall of Copan, where the dated monuments according to one computation come to an end at A D 800 The Mayan element in north western Honduras, on this argument, would represent settlements made on the dispersal which followed the fall of the Mayan Old Empire

Obituary Notices

Mr A J Greenaway

JOHN GREENAWAY, for so he was known to his numerous friends, died after a long illness at Mill Hill on August 25 He was born at Islington on July 12, 1852, the youngest of four children and only son of John Greenaway (1816–90) well known as a wood engraver and draughtsman from whom that great artist, Kate Greenaway (1846–1901)—the greatest and closest friend among many her brother ever possessed—derived her artistic inspiration

After his early education at a local private school, Greenaway was apprenticed to his father, but later by his own wish he was allowed to study chemistry and entered the Royal College of Chemistry in Oxford Street, and was appointed demonstrator under Sir Edward Frankland when the College was transferred to South Kensington. Among his pupils during that period (1872–81) were the late Profs W H and A G Perkin, with whom Greenaway maintained lifelong and intimate friendships In 1880, Greenaway became an abstractor for the Chemical Society, beginning an editorial connexion which lasted until his retirement in 1924 In 1885, he was appointed sub editor in charge of the Abstracts and after the death of his friend, Dr J C Cain, in 1921, he became editor

During the early part of his work for the Chemical Society, Greenaway lived with his sister, Kate, in the house at Frognal, Hampstead, which had been built for her After her death, he went to live at The Orchard, Chertsey, which was owned by Miss Ethel Boyce, a well known musician Through most of his life, Greenaway knew intimately great artists and musicians, particularly friends of his sister

Had it been possible for Greenaway to complete his chemistry training in Germany, as was then the custom, there is evidence that he might have become distinguished in his chosen profession. There is also evidence that had he not devoted his life to chemistry he might have become a distinguished artist. As it was, he was overburdened in his younger days with routine and irksome teaching from which he had to break away. In 1877, he published a paper, with the late R. J. Friswell, on thallous platinocyanide, and in 1881, while still teaching, he translated and edited, with the late Prof. W. R. Hodgkinson, Wislicenus's Short Text book of Organic Chemistry. At a time when he must have been fully occupied with editorial work he edited in 1891 the translation of the fifth edition of Mendeléeff's Principles of Chemistry; he also edited with the present writer a volume of the Faraday Lectures for the Chemical Society and he wrote a charming personal account of his friend, Prof. W. H. Perkin, who died in 1929. Greenaway became a fellow of the Chemical Society in 1874 and was elected a vice president in 1924. He was an original fellow of the Institute of Chemistry (1877).

For the Chemical Society, John Greenaway did outstanding and self sacrificing work and to him the Society must always be greatly indebted. He will long be remembered for his personal charm and modesty by many whom he taught to appreciate, as he did so intensely, beautiful things.

CHARLES S. GIBSON

WE regret to announce the following deaths:

Prof. S. Alexander, O.M., F.B.A., honorary professor of philosophy in the University of Manchester on September 13, aged seventy nine years.

Dr. Charles Carpenter, C.B.E., formerly president of the South Metropolitan Gas Company, on September 7, aged eighty years.

M. de La Baume Pluvinel, member of the Section of Astronomy of the Paris Academy of Sciences, known for his solar researches and for numerous instrumental developments, on July 18, aged seventy seven years.

Sir Basil Mott, C.B., F.R.S., president in 1924 of the Institution of Civil Engineers, on September 7 aged seventy eight years.

News and Views

Herman Boerhaave (1668-1738)

HERMAN BOERHAAVE, eminent alike as physician chemist and botanist, was born at Voorhuit, a village near Leyden, on December 31, 1668. He first intended to become a clergyman like his father, and after studying philosophy, theology and mathematics, qualified as a doctor of philosophy at Leyden in 1690 with a thesis on the distinction between the mind and the body. He then took up medicine, in which he qualified in 1693 with a dissertation on the importance of examining the excreta in disease. In 1702 he was appointed lecturer in the institute of medicine, his inaugural address being devoted to the importance of the study of Hippocrates. In 1709 he was made professor of botany and medicine, and five years later succeeded Bidloo in the chair of practical medicine, becoming in the same year rector of the University of Leyden. In 1718 he became professor of chemistry, on which subject he published several works, the most notable being 'Elementa chemiæ" (1724), regarded by Garrison as the best work on chemistry in the eighteenth century. His other principal works are 'Institutiones medicæ" (1708) and "Aphorismi de cognoscendis et curandis morbis" (1709). Moreover, in conjunction with Albinus, the greatest contemporary anatomist, he edited the collected works of Vesalius. In addition to Peter the Great, he counted among his pupils such eminent physicians as Haller, Pringle, Cullen, De Haen and van Swieten, the last of whom published a commentary on the Aphorisms. Boerhaave enjoyed a world-wide reputation, and many of his works were translated into different languages including Turkish and Chinese. His many honours included that of fellowship of the Royal Society and membership of the Academy of Sciences of France. His death took place on September 23, 1738.

Boerhaave Celebrations

THE Dutch Medical Association, the Leyden Faculty of Medicine and the Society of the History of Natural Sciences of Leyden are organizing a celebration beginning on September 23 to commemorate the two hundredth anniversary of the death of Herman Boerhaave. Visits will be paid to the old St. Cecilia Hospital, where Boerhaave gave clinical lectures, his country house 'Poelgeest" near Leyden and the village of Hardewyk on the Zuyder Zee, the seat of the ancient university where Boerhaave presented his inaugural thesis on July 15, 1693. A commemoration volume will be published.

The Royal Flemish Academy of Belgium

KING LEOPOLD OF BELGIUM has recently appointed the first thirty members of the Royal Flemish Academy of Belgium. The Academy comprises three classes: Sciences, Letters (including Political and Moral Sciences) and Fine Arts. A decree creating a Flemish Academy of Medicine may be expected to follow soon. This will form a complete equivalent of the old Académie Royale de Belgique, the official language of which is French. By thus putting both Academies on the same footing, instead of merely organizing a bilingual system within the Académie de Belgique, the Belgian authorities have achieved a further step towards cultural autonomy of the Flemish and French speaking parts of the kingdom —following upon the creation of the Flemish University at Ghent soon after the Great War. For the present, each of the three classes of the new Flemish institution will consist of ten members appointed by royal decree. Further members will be co-opted, the total number being confined to twenty per class.

THE original members are: *Sciences*: J. De Smedt, A. Dumon, W. Robyns, G. Verriest (all of the University of Louvain), J. Gillis, J. Meuwissen, A. Schoep, H. L. Vanderlinden, A. J. J. Vandevelde (all of the University of Ghent), H. Schouteden (director of the Congo Museum); *Letters, etc.*: P. Bellefroid (University of Nymegen), E. De Bruyne, H. J. De Vleeschauwer (both of the University of Ghent), E. Van Dievoet (University of Louvain), H. de Man and R. Victor (both of the University of Brussels), J. Denucé, C. Huysmans, F. Prims and F. Van Cauwelaert (all of Antwerp); *Fine Arts*: P. Gilson, L. Mortelmans, J. Van Nuffel, composers; C. Permeke, A. Servaes, W. Vaes, painters; H. Vandevelde, architect; E. Wynants, sculptor; S. Leurs, University of Ghent; R. Maere, University of Louvain. Provisionally, Messrs. Van Cauwelaert and Schoep will act respectively as president and secretary of the Academy, the full title of which is 'Koninklijke Vlaamsche Academie voor Wetenschappen, Letteren en Schoone Kunsten van België'.

Control of Nickel Distribution

IN a valuable paper on "The Control of War Metals as a Peace Measure", by F. E. Lathe and S. J. Cook, of the National Research Laboratories, Ottawa, the view is expressed that, although Canada produces more than 80 per cent of the world's output of nickel, control of distribution would not be a simple matter because only about 20 per cent of the annual production is used for war purposes, and the metal frequently passes through several hands before reaching the ultimate consumer. The calculations are based on 1934 figures, but the estimates are believed to be still substantially correct. The pamphlet has been forwarded to NATURE by way of comment on a suggestion made in the course of an article on "Science and a World Foundation" published in our issue of August 6, p. 227. Two further possibilities must be borne in mind. Reserves of the metal could be readily accumulated by the Government of a country which anticipated war; and, in the event of shortage, no effort would be spared to discover substitutes for essential metals. For an extended war, however, extremely large stocks would be required of such metals as iron and steel, copper, zinc and lead. The aim, therefore, should be to introduce restrictions of a temporary or unexpected character. But the only real hope of effective restriction lies in international action, and it would be most effective in the case of tin, antimony, nickel, copper and iron. This conclusion adds point to the proposal that scientific workers of all nations should, as a group, combine with other groups to give what help they can in promoting the evolution of a World State, capable when necessary of exercising suitable control over the distribution of such commodities.

Smoke-like Swarms of the Harlequin Fly

REFERRING to the letter from Mr. A. S. E. Ackermann entitled "A Curious Atmospheric Phenomenon", in NATURE of September 10, several correspondents suggest that the curious grey columns described by him were due to swarms of *Chironomus*, the Harlequin fly. Swarms of these insects dance about in the air at evening time and are commonly called 'gnats', to which they have considerable resemblance, though they differ from them in being entirely harmless. They often appear in columns on a calm evening and the columns may break up and re-form with a wavy motion. Capt. C. T. P. Cave writes: "I once saw a number of such columns on a very still evening in Lombardy. At first I took them to be very small narrow pillars of smoke from burning weeds, but a closer view showed them to be swarms of gnats. The whole description given by Mr. Ackermann tallies with my recollection of the phenomenon."

National Museum of Southern Rhodesia

DR. G. ARNOLD, director of the National Museum of Southern Rhodesia, Bulawayo, writes to point out that some confusion would appear to have arisen in reference to the proposal to establish a museum for Zimbabwe, reported incorrectly to be intended as a 'National' museum (see NATURE, July 9, p. 65). The proposed museum, Dr. Arnold states, is to be a small one-roomed building, in which will be exhibited some of the original antiquities which have been found in that neighbourhood, and also plaster casts of finds which are now the property of the British Museum and of other museums in Southern Rhodesia and Cape Town. The National Museum of Southern Rhodesia, already in existence at Bulawayo, was formerly the Rhodesian Museum, which was founded in 1901 by the Rhodesia Scientific Association and the Rhodesia Chamber of Mines jointly. From 1902 the Government of Southern Rhodesia contributed to maintenance an annual grant equal in amount to the subscriptions guaranteed by the founding bodies and an annual contribution from the Bulawayo Municipality; but in 1936 the Government, acting on a recommendation made by the Museums Commission, of which Sir Henry Miers was chairman, took over the Museum under an Act of Parliament of Southern Rhodesia, and constituted it the National Museum of Southern Rhodesia. The control is vested in a Board of Trustees appointed by the Governor. It includes departments of zoology, entomology, geology, and ethnology, prehistory and national history. Under the provisions of the Act, the Board is also empowered, subject to the approval of the Governor, to acquire by agreement any existing museum in the Colony, and also, if directed by the Governor, to establish and maintain any new museum in the Colony. The number of visitors in the first year under the Board of Trustees was 24,585, excluding natives, and in the year ending December 31, 1937, 23,501.

The Carnegie United Kingdom Trust

So all pervasive are the Trust's activities that its annual report (Twenty-fourth Annual Report, January–December 1937, approved by the Trustees at their General Meeting held on Friday, March 4, 1938. Pp. vi+92+2 plates. Dunfermline: Carnegie United Kingdom Trust) is almost equivalent to an index to all organized voluntary effort toward social amelioration. It is noteworthy that a very large proportion of the enterprises favoured by the Trust are concerned with rural life: land settlement, rural community councils, village halls, survey of Scottish villages, local history records, schools for rural music conductors, young farmers' clubs, women's institutes, youth hostels, Y.M.C.A. farm training scheme, village colleges, women's rural institutes' handicrafts scheme. Land settlement schemes, for which the Trust allocated £150,000 for the period 1936–40, progressed steadily last year. The Land Settlement Association now controls twenty-five estates in fifteen English counties, comprising 11,000 acres and providing, when fully developed, small holdings for 7,000 persons, all taken from distressed areas. The settlers who are definitely established are happy in their surroundings and are mixing more and more with the old inhabitants of neighbouring villages, and the general health, especially of the children, has shown notable improvement. The Association is, however, finding it difficult to induce local authorities to make use of the powers vested in them. For many years, the Trust has fostered the development of agencies for caring for the welfare of boys and girls over fourteen years of age. Among these are the National Association of Boys' Clubs and the National Council of Girls' Clubs, which are in receipt of subsidies from the Trust amounting to £25,000 for the current quinquennium. Valuable as the work of these clubs undoubtedly is, it is very small in volume when compared with the corresponding activities in Germany and Italy.

The Agricultural Research Council

Farmers and others interested in agriculture have sometimes expressed the view that insufficient information is available about the activities of the Agricultural Research Council. To meet what it recognizes as an important need, the Council has issued a booklet entitled "Constitution and Functions of the Agricultural Research Council", copies of which can now be obtained on written application to the Secretary at 6a, Dean's Yard, Westminster, S.W.1. The Council, which was established by Royal Charter in 1931, is responsible for tendering advice to the Ministry of Agriculture and Fisheries, the Department of Agriculture for Scotland and the Development Commissioners as to the expenditure on agricultural research of State funds amounting to more than four hundred thousand pounds yearly. It is also charged with the scientific supervision of subsidized agricultural research, and, in addition, it has research officers engaged in the investigation of particular problems. A recent development has been the acquisition of an estate at Compton in Berkshire for use as a field station. Here problems such as those involved in certain diseases of animals will be investigated on a field scale, when the necessary laboratory experiments have been carried out at the research institutes, and a supply of animals, which have been raised in isolation and are free from disease, will be kept available for the workers at these institutes. In addition to advising on research in progress, the Council plans and co-ordinates such immediate extensions of the research programme as seem necessary to secure a more intensive attack on problems of special urgency, particularly in the field of animal and plant diseases.

Nomenclature in Electrical Engineering

The development of electrical science and its applications during the last century has led to the introduction of a host of names, units and definitions, many of them now household words. The history of these words, and of others which have been introduced, only to be discarded, is of considerable interest, and recalls the difficulties the pioneers experienced in explaining clearly new facts and phenomena. Though many terms go back to Greek science and to the sixteenth, seventeenth and eighteenth centuries, the majority belong to the last century and the days since Faraday. The subject is an intricate one and it has not, we believe, been dealt with before so fully as by Prof. G. W. O. Howe, in a paper entitled "The Concepts and Language of Electrical Engineering" read to the Association of Engineers at Calcutta, and printed in the *Engineer* of September 2. In coming the words anode, cathode, ions, electrodes and others, Faraday was assisted by Dr. Whewell of Cambridge, whose encyclopædic knowledge led someone to write, "You may roam where you will through the realm of infinity, and find nothing so great as the Master of Trinity." Whewell had proposed the terms inductricity and inducteous, which fortunately, like the mac, bob, tom and dick of Heaviside, were not adopted. Prof. Howe does justice to the various individuals who have devoted their attention to the matter of units, as well as to the committees and congresses which have assisted in standardizing them.

Indian Forest Research

The value of forestry research work in its direct bearing upon other Government departments and industry is admirably portrayed in a publication entitled "Forest Research and Indian Industry", issued by the Government of India Press, New Delhi. Experts are maintained at the Forestry Research Institute at Dehra Dun to undertake research work in sylviculture, botany, mycology, forest protection, entomology, biochemistry, forest utilization, wood technology, timber seasoning, preservation and testing of timbers, wood working and minor forest products including paper pulp. The work of these experts often interlocks, as becomes evident from a perusal of this very informative publication. Illustrative of some of the sylvicultural work undertaken at the Institute is a recent paper in sylviculture entitled "Seed Weights, Plant Percents, etc, for Forest Plants in India", by J N Sen Gupta (Ind Forest Records, New Series Sylvic, 2, No 5, Government of India Press, New Delhi, 1937). In this paper the author gives data for the date of collection, seed weight, germinative capacity and germination per cent of 505 tree species, including 52 exotics, from all parts of India. In the botany section, Mr C E Parkinson published two numbers dealing with Indian tree species in the *Indian Forest Records*, New Series, Botany (Govt of India Press New Delhi, 1937). The first (1, No 1) deals with the important Indian *Terminalia* of the section *Pentaptera* comprising trees of forest and economic importance. Four species with three varieties and nine forms are recognized. No 2 of vol 1 is devoted to part 4 of Illustrations of Indian Forest Plants the paper dealing with five species of the family *Dipterocarpaceæ*.

Broadcasting Station LS-1, Buenos Aires

THE broadcasting station LS-1 belonging to the municipality of Buenos Aires and situated about 20 miles from the city, has recently been re equipped and is now one of the most powerful in South America. The antenna is the tallest vertical broad cast radiator in South America, being 778 feet high. It uses the new shunt excitation method developed by the Bell Telephone Laboratories, a full description of which is given in their quarterly *Journal* of July. The ground system consists of 120 buried radials, each 670 feet long with an equal additional number of radials each 280 feet in length. Power is fed on to the antenna system through a 62 ohm nitrogen gas filled concentric copper tube transmission line, 640 feet long. The station is operated under the administration of the Colon Theatre of Buenos Aires, which is one of the world's finest opera houses, where many of the world's leading artists are heard each season. There are 16 hours of transmission daily, with a varied programme of widely international flavour and cultural and educational subjects. Its main feature is the complete transmission of the opera and other musical activities of the Colon Theatre. The Colon season was officially opened this year by the President of the Republic on May 23, and can now be heard by the great majority of the population of Argentina as well as by listeners in Chile, Uruguay and southern Brazil. A wide repertory of classic Italian, German and Russian opera has been presented in addition to a few modern Argentine works. The new studios are built below ground level and close to the Colon Theatre and are completely sound insulated. From the broadcasters point of view the economy and ease of operation have set up new standards. The audio frequency response does not vary more than one decibel between 30 and 10,000 cycles. The audio distortion is less than 5 per cent even at complete modulation. Provisions have been made for increasing the output of the 50 kilowatt transmitter to 500 kw by the addition of a 500 kw amplifier. The results obtained have more than equalled expectations.

The Smithsonian Institution

THE report of the secretary of the Smithsonian Institution for the year ended June 30, 1937, refers to the improvement of the National Zoological Park by the completion of three new exhibition buildings, a machine shop, a garage and new heating and electric installations. An expedition to Sumatra to obtain specimens of the interesting animals of that region for the National Zoo was still in the field, but reports indicated that it was highly successful. In the Division of Radiation and Organisms, notable advances have been made in the studies of photo synthesis phototropism and the action of ultra violet rays on plant growth. The Astrophysical Observatory has continued its measurements of the solar constant of radiation and a new method has been devised in place of the 'short method' reduction of observations used since 1923 in which a flaw was discovered. The Smithsonian radio programme a weekly half hour presentation of the Institution's researches and activities, continued with undiminished popularity, and accessions to the Library for the year number 11 469 mostly in exchange for the publications of the Institution. Appendixes include the report of the United States National Museum the National Collection of Fine Arts the Freer Gallery of Art and of the several divisions of the Institution.

Smallpox Vaccination in an Indian Epidemic

A STRIKING instance of the protection against smallpox afforded by vaccination is given in the annual report for 1936 of the All India Institute of Hygiene and Public Health, Calcutta, recently published. During the smallpox epidemic that occurred in the first quarter of 1936, there were 604 infants and children less than five years of age on the roll of the Maternity and Child Welfare Section of the Institute. Of these children 434 were vaccinated before or during the epidemic, and 170 were not vaccinated. Of the unvaccinated 42 developed the disease, a case incidence of 24 7 per cent, of whom 17 died, a mortality of 10 per cent for the group or of 38 5 per cent of the cases. In the vaccinated group, 10 developed the disease in less than a week after vaccination and before protection had developed of whom 7 died. Excluding these cases, of the remaining 424 vaccinated efficiently only 3 contracted the disease and all recovered an incidence of 0 7 per cent with mortality *nil*.

Gastro-Enteritis Conveyed by Raw Milk

AN outbreak of food poisoning occurred at Wilton, in Wiltshire, in October 1936 and was limited to consumers—chiefly children—of a particular supply of bottled raw milk (A Report on an Outbreak of Food Poisoning due to Salmonella, Type 'Dublin' and Conveyed by Raw Milk. By E T Conybeare and L H D Thornton. Reps on Pub Health and Med. Subjects, No 82. Ministry of Health, 1938. H M Stationery Office 2*d* net). The attack of illness commenced in 12–24 hours after consumption of the milk, the chief symptoms being headache, nausea and vomiting, and later diarrhœa, persisting for 1–3 days, and though the attacks were severe, there were no deaths. As the outbreak was not recognized for some days, bacteriological examination of the patients proved negative. However, from a specimen of the milk delivered on October 29, a *Salmonella* food poisoning organism was isolated, afterwards identified as being a 'Dublin' type, and four days later the same organisms was again isolated from milk supplied by the same producer. Confirmatory evidence was obtained by serological tests of the blood of nine convalescents, whose blood showed specific agglutination for type Dublin in high dilution. Examination by agglutination tests of the herd of 51 cows supplying the milk picked out three cows with a high agglutination for the 'Dublin' type. Specimens of milk and dung from these three cows were examined. The milk from all three and the dung from two were negative, but from the dung of the third animal a heavy growth of *Salmonella* Dublin type was obtained, and this carrier cow was removed from the herd, and no further trouble ensued. It is remarked that no amount of care in milking and distribution of such a raw milk could prevent it from being a danger to the consumer.

Insulators

A SEVEN-PAGE article on "Recent Developments in Electrical Insulating Materials" by Dr. L. Hartshorn (*J. Sci. Inst.*, July) will prove of great use to constructors of electrical apparatus and will serve as a base from which research on the properties of insulating materials advocated by the Radio Research Board may operate. The author describes the properties of ebonite, of loaded ebonites, of synthetic resins which can be readily moulded or used to bond laminated material into insulating boards, and when of the hydrocarbon type have dielectric constants little more than 2 and power factors so low as 2×10^{-4}. Ceramics provide insulators of the steatite group depending mainly on magnesium silicate, and of the rutile group, principally titanium dioxide, used in the construction of condensers. After shaping, both are fired and cannot afterwards be worked without difficulty. They are apt to absorb moisture which alters their properties. Certain waxes, for example, the chloronaphthalenes, have high dielectric constants and fairly low power factors. A table of dielectric constants, power factors, resistivities, mechanical and electrical strengths and softening temperatures for nearly thirty insulators is given.

Photography in X-Ray Departments

THE brochure on "X-Ray Materials and Accessories", published by Messrs. Kodak, Ltd., might well contain the word 'photographic' did not the name of Kodak at once conjure up the word; its forty pages are devoted to a description of photographic supplies for medical and dental X-ray work. Routine work demands rigid control of variables for its quick effectiveness, and this firm has realized that, provided the actual exposures are reasonably correct, the development of X-ray films can be standardized by the use of reliable reagents, proper timing and regulation of the working temperatures. In the planning of X-ray departments, insufficient attention is sometimes given to the developing and printing rooms, where laborious hours are spent in semi-darkness. Efficient planning should reduce these hours to a minimum, and the experience of Messrs. Kodak is at the service of those planning and being responsible for the photographic work in X-ray departments.

Handbook of International Organizations

AN English edition of the Handbook of International Organizations has now been issued by the Secretariat of the League of Nations. This volume of nearly 500 pages gives the particulars of nearly 760 international organizations, including addresses, names of officers, notes on finance, objects and activities. International bureaux under the direction of the League, official central bureaux and private associations and federations in so far as they have international objects and are not run for profit are included. These organizations are classified in the following groups to facilitate reference: politics and international relations; religion; arts and sciences; education; students and university organizations; medicine and hygiene; law and administration; press; feminism; labour and professions; agriculture; economics and finance; trade and industry; communications and transit; sport and touring; and miscellaneous. The utility of the volume is increased by the provision of a subject index, an alphabetical index and a geographical index. The latter indicates that 183 of the organizations have their seats in France and 140 in Switzerland, Great Britain coming next with 78 organizations and Belgium being fourth with 77.

Recent Earthquakes

THE violent earth tremors which were experienced on Monday, September 5, over a considerable area about fifty miles south of Algiers (*The Times*, Sept. 7) cannot be said to have affected an area where earthquakes of destructive intensity are usual. Small tremors are, however, quite common, especially where the land shelves steeply to the ocean deeps. Between 1911 and 1931, Mme. A. Hée listed 586 tremors, distributed in twenty-two different zones, only four of which reached destructive intensity. The observatory of Alger Bouzaréah is actively engaged in recording and studying these local earthquakes, and we anticipate more information at a later date. An earth tremor shook Colombo, in Ceylon, early on Sunday, September 11, but no damage is reported (*The Times*, Sept. 12). In this zone severe earthquakes are practically unknown. Slight earthquakes are common along a line through Madras passing south-south-west near the southern edge of the Deccan of India, and these are often in sympathy with larger ones occurring in northern India, a fact which may be attributable to the strained condition of the peninsula. The Ceylon tremor was most probably a local surface shock due to slipping along a fault. Another strong shock was recorded by the Stuttgart Seismological Station on Sept. 7d. 4h. 15m.

BRITISH ASSOCIATION DISCUSSIONS

Significance of the Swanscombe Skull

THE repertoire of the human palæontologist has recently been augmented by the discovery of portions of a fossil skull at Swanscombe, in Kent. The importance of this find was given recognition by allotting a morning session of Section H (Anthropology) for its discussion.

The Swanscombe 'skull' actually consists of two bones only, the occipital and left parietal, both of which are extremely well preserved. Their interest is related to the fact that they were found in interglacial deposits containing a Middle Acheulean industry, and that their antiquity is about as well attested by geological and archæological evidence as that of any human fossil is ever likely to be. To Mr A. T. Marston belongs the honour of having discovered the two bones of the Swanscombe skull. He came upon them at separate times, in June 1935 and March 1936, 24 ft. below the surface in the well stratified gravels of the Barnfield Pit at Swanscombe. The parietal bone was actually found by Mr. Marston *in situ*. Although separated by a distance of 8 yards, the bones are practically unworn, and articulate perfectly with each other. Moreover, they show the same state of preservation as the fossil mammal bones with which they were associated.

The deposits at Barnfield Pit are the Middle Gravels belonging to the 100-ft. terrace of the Thames; they are later in date than the Great Chalky Boulder Clay, and they are definitely interglacial deposits. Prof. W. B. R. King is of opinion that they were laid down between the Great Eastern glaciation of East Anglia and the cold period represented by the main Combe Rock of the Thames valley. This conclusion is borne out by Hinton's study of the associated fauna. *Elephas antiquus*, *Rhinoceros megarhinus*, *Rhinoceros hemitoechus* and *Dama clactoniana* bear witness to an interglacial facies. There were also found associated with the human skull bones remains of *Cervus elaphus*, *Bos primigenius* and *Equus caballus*.

The archæological associations of the Swanscombe skull have been studied by C. F. C. Hawkes. The flint implements from both upper and lower levels of the Middle Gravels (including the channel in which the skull bones were found) belong without doubt to the Early Middle Acheulean hand-axe industry (Acheulean III of Breuil). The complete absence of any sign of a distinct Levallois industry makes it impossible to allocate these implements to a later Acheulean phase. It is interesting to note that, in the Somme valley, deposits containing a Middle Acheulean industry are commonly assigned to so early a date as the Mindel-Riss interglacial period, and this corresponds to Zeuner's interpretation, on geological grounds, of the Barnfield Pit deposits.

It is unfortunate that while the geological, archæological and faunal evidence related to the Swanscombe find is so complete, the skull itself is very incomplete. Clearly it would be unbecoming for an anatomist to attempt to draw any far-reaching conclusions, in regard to the skull as a whole, from the study of an occipital and one parietal bone. Since the sutures remain still unobliterated, the bones evidently are those of quite a young individual. The age of the latter is estimated to have been twenty to twenty-five years. Since, also, the muscular impressions are rather poorly marked in relation to the size and thickness of the skull, the sex of the individual is judged to have been more probably female than male. First inspection reveals at once that—apart from their unusual thickness—the bones are quite closely comparable with those of a modern human skull. The probable cranial capacity—as inferred by comparative studies of recent human skulls whose parietal and occipital bones show similar dimensions and curvatures—has been estimated by Morant to be 1 325 c c This figure of course is conjectural but it remains certain that the cranial capacity of the Swanscombe skull was well within the range of variation of modern man

Since the two bones articulate perfectly with each other the various dimensions and indexes of the back part of the skull can be compared accurately with those of recent skulls The result of such a study leads to the interesting conclusion that the Swanscombe skull is astonishingly similar in all its main metrical features to the average of available series of modern skulls The height of the skull (basi bregmatic) and the maximum bi parietal width are indeed rather greater than the corresponding measurements of female British skulls The inclination of the plane of the foramen magnum shows nothing exceptional The occipital bone is rather unusually broad but even this character falls within the range of variation of recent British skulls

A minute study of the morphological features of the Swanscombe bones shows only two characters which may be considered of unusual significance These are the general thickness of the bones and the extension backwards of the sphenoidal air sinuses into the basi occipital This latter feature certainly does occur occasionally in modern human skulls but it must at least be very rare for it to be found in a skull so young as the Swanscombe fossil Possibly it indicates a rather strong development of the accessory nasal air sinus system as a whole which may have been associated with a fairly massive development of the facial region of the skull The thickness of the bones although it can be readily matched at some points in recent skulls appears to be exceptional in certain regions such as the cerebellar fossa of the occipital bone and the antero inferior angle of the parietal In this character the Swanscombe fossil shows an interesting resemblance to the Piltdown skull Indeed Sir Arthur Keith believes that the two are very closely related morphologically However since the remains of both are so fragmentary this cannot be confirmed or refuted

Lastly the endocranial cast of the Swanscombe bones calls for consideration This shows clearly that the brain was quite richly convoluted and it provides no certain evidence that the convolutional pattern was any more primitive than that of modern human brains Reference should perhaps be made to a curved furrow in the right occipital region of the cast which might be interpreted as a lunate (or simian) sulcus of a very primitive type Apart however from the general difficulty of identifying sulcal impressions on endocranial casts of human skulls this furrow (if indeed it does represent a sulcus at all) may equally well be interpreted as what the late Sir Grafton Elliot Smith termed a pseudo lunate sulcus that is a sulcus sometimes found in the occipital lobe of modern human brains which merely simulates a sulcus of the simian type The endocranial cast shows localized expansions over the parietal and temporal lobes which have been described in casts of certain other fossil human skulls and which have been regarded by some authorities as having a special significance in the later stages of the evolution of the human brain However similar localized eminences are sometimes to be seen on endocranial casts of modern human skulls hence little importance can be attached to them There is indeed little doubt that the endocranial cast of the Swanscombe skull would quite well pass for that of a modern skull It indicates clearly that the brain of Middle Acheulean man had already acquired a morphological status comparable with that of modern man a conclusion which is somewhat remarkable in view of the fact that he is commonly presumed on geological evidence to have lived during the Mindel Riss interglacial period the antiquity of which according to Zeuner s geochronological data must be reckoned at about 250 000 years

It is necessary to emphasize that we have no sure evidence regarding the construction of the front part of the skull in the Swanscombe fossil The frontal region and the face and jaws *may* have shown unusual features which would quite definitely separate Swanscombe man from *Homo sapiens* On the other hand it is reasonable to suppose that if these features had been of an extreme type they would certainly be reflected in the anatomy of the occipital and parietal bones Morant has shown that *Homo neanderthalensis* can be distinguished from *Homo sapiens* by the metrical characters of the parietal and occipital bones alone This however is not the case with the Swanscombe bones

In summary it may be stated that *on the evidence of the fragments available* the remains of the Swanscombe skull suggest that Acheulean man was not distinguishable on morphological grounds from *Homo sapiens* This conclusion is by no means at variance with the implications of recent discoveries of fossil man such as the Ehringsdorf skull the Steinheim skull and the Mt Carmel skeletons for these have already provided evidence that there existed in Europe in pre Mousterian times a type of mankind approximating much more closely to *Homo sapiens* than the Neanderthal type which is characteristically associated with the later Mousterian culture

W E Le G C

Ritual

IN the symposium on ritual held by Section H (Anthropology) at Cambridge on August 23 several points of interest emerged All the speakers agreed in rejecting the shallow view mentioned only to refute it by Mr A M Hocart that ritual is primarily a matter of the emotions On the contrary it is likely to be disorganized and made degenerate by the presence of too much emotion although the utter absence of such a motive force may render it like every other human activity a dead and mechanical thing no longer of significance

Instance after instance may be given and was indeed given especially by Mr Hocart in the first contribution to the discussion of ritual being built up and elaborated by the cool it might almost be said the scientifically logical working of relatively enlightened minds those of the noble or more especially the priestly class of a race on its way to civilization for as Mrs Chadwick rightly insisted in her address one of the most fruitful supplies of material is the rites of barbarous peoples whose ceremonial is not written down and so is perhaps less likely to become a fossil When an emotional wave sweeps up from the lower and less enlightened strata of the people the dignified structure which has been erected is all too likely to be disintegrated and even to degenerate into the merest grunts and howls the beast like expressions of primary emotions fear or what not Yet at the same time it should be remembered (a point incidentally made by Prof H J Rose) that some of the highest manifestations of the religious life whereof we have any record transcend ritual expression by as much as these outbursts of primitivism fall below it

Once ritual has started from whatever source its contents and immediate intention may vary considerably It may have for its sole or its principal object the setting forth of some piece of traditional lore perhaps (again the point was Mrs Chadwick s) the whole or the principal learning of the people to whom it belongs There is such a thing as instructing a barbarous folk by means of a religious ceremony with a complicated rite In New Zealand for example in parts of Polynesia among one or two peoples of Africa the priests are genuinely the educators of their flock the scholars and teachers of the nation and their rites have apparently for at least one of their objects the production of a suitable emotional state among the hearers preparatory to impressing on their minds the doctrines which it is thought important that they should know It is not necessary that what the average European would consider religious instruction should then follow there are rites including chants or other literary forms which have a not inconsiderable historical content though not everyone perhaps would be so optimistic as Mrs Chadwick as to the amount of the history of illiterate peoples which we can now recover from these products of their literary and religious authorities

A characteristic and important form of ritual is that which has for its contents a myth This was the subject of Prof S H Hooke s address wherein he dealt cautiously with some highly controversial points There are of course myths which are purely etiological existing for no other purpose than to explain why such and such a piece of ritual is gone through They are generally pure speculation and have nothing to do with the real origin and purport of the rite But there are others (Prof Hooke instanced the stories of Ishtar and Tammuz of the Creation and of the Deluge) which are veritably the content of ritual it existing to set them forth not they to explain it The line is often vague and hard to draw but it is there and can be perceived if the examiner is expert enough

Prof Rose dealt mostly with magic as a content of certain forms of ritual He used the word in Frazer s sense without accepting Frazer s theories of its relation in time to religion There are actions of man intended to have a direct effect upon some thing in his environment (especially something quite outside his real control such as the weather) without invoking the active or passive concurrence of any power superior to man or different from him Ritual (an example from ancient Rome was given—the ceremonial of the Lupercalia) may consist of such actions arranged like all rites in a pattern or complex intended and supposed to be more effectual than a single action of the kind would be Unlike those ritualists who dramatically set forth the doings of gods or heroes (although there is little doubt that such actions as theirs may also be magical the re doing of some mythical deed which was powerful of old in hopes that it may be efficacious to day) operators like the Roman Luperci were doing things meant to be as practical and perhaps as little mystic as the actions of the most commonplace workman who digs a drain that water may run away or builds a fence that beasts may be kept out They made themselves temporarily into goats in order to put the desirable lustihood of the goat into their little Palatine community and at the same time to scare away the undesirable qualities of the wolf the really formidable and reputedly uncanny enemy of their flocks and herds to say nothing of their children

Summing up all that was said it seems to be fairly well made out that ritual is a complex phenomenon not to be explained away by any over simple formula psychological or other and that its purpose once it is established and indeed in its establishment may vary within very considerable limits That its various kinds may interact upon each other and any given ritual may have been produced by cool priestly reasoning modified by the enthusiasms of the laity be originally magical in its intent strengthened to that end by the addition of a venerable myth and finally misunderstood as being somehow pleasing to a god who had perhaps nothing whatever to do with it at first is a proposition which none of the speakers tried to controvert though more than one showed that he was ready if need be to subscribe to it

The 'Middle Palæolithic'

IN the course of the recent meeting of the British Association at Cambridge Section H (Anthropology) held a symposium on the Middle Palæolithic While it cannot be said that the question was completely dismissed in one afternoon certain important points were dealt with

The expression Middle Palæolithic has itself become ambiguous and is no longer used by the majority of prehistorians At the same time it appears in some of the older literature and its retention has now and again led to unfortunate misunderstandings Originally it was somewhat loosely used to denote those western European cultures which follow immediately after the Micoquian and precede the Aurignacian These cultures are more properly described as the later phases of the Levalloisian—Levallois V VI VII—and the true Mousterian—that is to say the culture of the La Chapelle aux Saints variety of Neanderthal man But clearly used thus the term Middle Palæolithic was not properly speaking an expression of time like Middle Pleistocene and it was obviously unsatisfactory arbitrarily to cut across an evolving culture like the Levalloisian The content of the phrase has therefore grown to include all the cultures before the Aurignacian the industries of which were for the most part made from flakes as is the case with the Mousterian and Levalloisian in contradistinction to the *coup-de poing* core tool culture or cultures

These flake tool industries are not all similar they seem to have been the products of allied though slightly differing cultures Even in Europe alone there are not a few and to them distinct names have been given Cromerian Clactonian Levalloisian Tayacian Weimar Mousterian etc Their distribution was sometimes fairly wide sometimes very restricted each of them had a beginning evolved and came to an end their period of existence was sometimes long sometimes short all were not contemporary but many of them overlapped in time Some of them were in part contemporary with the wholly different *coup de poing* culture or cultures but distribution maps show that these two great culture groups civilizations or culture cycles[*] are quite distinct though a line of contact occurs between them in north eastern France and Belgium and in south eastern England Speaking generally one can say that the cultures comprising the flake tool civilization are found from the North Sea to China and those of the core tool civilization in Western Europe only and southwards over most of Africa It would seem that we are thus faced with the fact that as early as a period preceding the Upper Palæolithic and in fact forming the Lower Palæolithic there existed in the world at least two quite distinct civilizations or culture cycles each made up of a greater or smaller number of differing though allied cultures The question of nomenclature is therefore of the greatest importance

Our orthodox terminology is based on that propounded during the last century by Gabriel de Mortillet when describing the sequence of cultures found in France From the foregoing it would seem now to be quite erroneous to name a culture of the flake tool civilization found outside France by the French name—unless for some reason it appeared probable that the two cultures concerned were not merely allied but identical The term Mousterian for example should on these grounds be restricted to the French culture the industries of which are so well known and are incidentally the products of a particular branch of Neanderthal man It simply confuses the issue to use the name to describe allied industries found elsewhere in Europe the product of differing though related cultures simply because both belong to the same culture cycle Still worse is it to use this term (or perhaps equally such terms as Clactonian etc) to describe industries found in such far flung parts of the world as South Africa—where perhaps the very excellent work of Mr A L Armstrong in S Rhodesia provides a case in point—or India In the same way the term Moravian should be applied to the culture belonging to the Upper Palæolithic civilization in Moravia which though more or less contemporary with the Magdalenian of France and clearly related to it yet differs from it in many essential ways

---

[*] I retain the term civilisation because it has been used in previous publications but I am inclined to agree with the opinion expressed to me some time ago by Prof. Gordon Childe that the term 'culture cycle which has no popular connotation, would be more satisfactory

Sir Arthur Keith has come to an interestingly similar conclusion from the point of view of the physical anthropologist For the period under review he recognizes in Europe a general type *Homo neanderthalensis* But in various parts of the Continent he distinguishes various modifications the Chapellian Ehringsdorfian Krapinian while outside Europe he equally distinguishes a Palestinian The number of these modifications may well be increased as knowledge increases and will indeed probably be found to coincide with the different cultures of the civilization But all the time it can be said that the civilization or culture cycle as a whole is the product of an undifferentiated *Homo neanderthalensis*

In actual practice a nomenclature may take the form of terms denoting (*a*) time such as early middle or late Pleistocene (*b*) typology and technology which are generally descriptive terms like blade and burin core flake etc and (*c*) culture which are generally place names like Mousterian Acheulean etc The wrong use by prehistorians of culture names to describe techniques or time spans is in almost every case to be deplored In this connexion we are grateful to Miss Garrod for a good example of the dangers of determining culture or age solely from typological and technological considerations The flake tool industries from Ehringsdorf and also from Taubach which she has recently been studying are on geological and faunal grounds definitely earlier in date than the true Mousterian yet she points out they do resemble very closely the later industries of that culture in France

Flake tool industries occur profusely in East Anglian gravels and certain gravels of the Lower Thames area have also yielded thousands of specimens The problem of their exact horizon and date is one for the quaternary geologist towards the solution of which such investigators as Messrs King Oakley Zeuner and Paterson are strenuously working—but a lack of clarity in the archæologist s nomenclature will here only make confusion worse confounded

MILES C BURKITT

Animal Locomotion

A SERIES of papers read at a symposium in Section D (Zoology) of the British Association at Cambridge on August 23 brought into prominence the recent progress which has been made in the study of animal locomotion The movement of a fish an insect or a bird present problems in kinematics which are closely related to those of a torpedo or aeroplane and it is therefore not surprising that they have been or are being solved by methods more familiar to engineers than to zoologists

From observations of the behaviour in a wind tunnel of a carefully prepared model Dr J E Harris has been able to express the functions of the paired and unpaired fins of a dogfish in terms which give a relatively precise hydrodynamical picture of the whole system He has shown also that the well known transition from an asymmetrical heterocercal tail to one in which the dorsal and ventral flukes are equally developed can be correlated with the development of a swim bladder and with a change in the function of the pectoral fins The latter structures are essentially 'elevating planes in the dogfish whereas in many teleosts they have become modified into a very efficient braking system for a fish carrying out a rectilinear glide There seems little doubt that the changes in position and size of the various fins which have occurred during evolution are to be correlated with the operation of comparatively simple hydrodynamical principles

A very successful application of aeronautical principles to animal flight has recently been made by Dr F S J Hollick By a variety of ingenious methods he has been able to demonstrate the precise movements executed by the wings of a fly during active unrestricted flight The use of an extremely delicate system of balances has made it possible to demonstrate the direction magnitude and point of action of the forces acting on the body of the fly when its wings are in motion A combination of these data with those made on the reflex effect of a moving optical image has enabled Dr Hollick to give a convincing picture of the manner in which a fly on approaching the ceiling of a room is able to change its direction of motion through 180° in a vertical plane and so attach its feet to the ceiling It is to be hoped that the publication of these interesting and important experiments will not be unduly delayed. It would be of great interest to extend this work to a study of bird flight, particularly in view of Mr Horton-Smith's recent observations on the flight of gulls.

It may, perhaps, be claimed that the main problems of soaring flight of birds are approaching solution, although definite observations concerning the function of the bastard wing and other anti-stalling devices are as yet few in number The study of 'flapping' flight presents much greater difficulties. Mr. Horton-Smith's photographs, obtained by high-speed cinematography, show clearly the detailed movements of the wings of gulls during both phases of their beat, and open up the possibility of applying aeronautical methods of analysis with hope of success. There can be little doubt that a careful investigation of the properties of various types of wings when exposed to air currents of known strength and direction would yield valuable results It is of interest to note that a suitable wind tunnel has recently been built in the Zoological Department at Cambridge by Mr. R. Brown, whose work, together with that of Mr. Horton-Smith, will be followed with interest

To the biologist, a solution of the mechanical problems of animal locomotion is a prelude to a study of the physiological principles which control the co-ordination of the locomotory muscles. The discussion at Cambridge largely centred on an assessment of the role of environmental stimuli in the maintenance of a locomotory rhythm. The evidence presented by Prof J. Gray and Dr. H. W Lissmann shows that in many, if not in all, terrestrial invertebrates the maintenance of an ambulatory rhythm is dependent upon a background of tactile stimulation from the substratum In the absence of such stimulation, the ambulatory rhythm either ceases or gives place to a swimming rhythm of totally different nature to itself. In a few instances, notably the nemertine *Cerebratulus*, one region of the body may exhibit a typically terrestrial pattern of movement whereas another, if submerged in water, may execute a swimming rhythm of different nature and frequency. The role of environmental stimuli as pace-makers for the various phases of an ambulatory cycle is clearly defined in many invertebrates, and in forms such as the myriapods, the phase difference between adjacent limbs is determined by environmental factors At the same time, the persistence of an ambulatory rhythm in the desensitized limbs of vertebrates (first observed by Sherrington and by Graham Brown) demonstrates that in vertebrates, in any event, all environmental stimuli probably operate on bilaterally arranged centres in the spinal cord, which are capable of displaying a rhythm so long as both sides are receiving an approximately equal intensity of stimulation, whether the source of this stimulation be central or peripheral Under natural conditions, the locomotory centres are probably responding to stimuli from both these sources . when the animal is walking, the peripheral stimuli are dominant both in intensity and in qualitative effect ; when the animal is swimming, the central stimuli are probably of primary importance

So far as is known, no invertebrate central nervous system can display a locomotory rhythm after complete isolation from the periphery, but experiments with the common leech (*Hirudo medicinalis*) show that the whole nerve cord can exhibit a co-ordinated electrical rhythm so long as a limited number of ganglia at one end of the animal retain their connexions with active musculature.

The Mechanism of Evolution

THE discussion on the mechanism of evolution, which occupied Sections K (Botany) and D (Zoology), meeting together, for the whole of August 19 at Cambridge, was an important event.

Taken together with a discussion on "Natural Selection" held by the Royal Society about a year ago, and one on the "Irreversibility of Evolution" at the Christmas meeting of the Society of Experimental Biology, it marks the end of that long period during which biologists in general had lost interest in the subject, because it seemed incapable of investigation by quantitative or experimental methods. This great change has been brought about by the recent developments in genetics and in nuclear cytology.

The discussion included certain contributions which stated some of the conditions which have resulted from organic evolution in such a manner that they could be discussed Dr. J. S. Huxley spoke on "Character Gradients", showing that in many cases, especially among birds, but also in mammals, insects and plants, characters are found to vary regularly in a definite way with distance from a selected starting point. Thus the length of the wing in migratory birds tends to become greater in collections made farther and farther north. The change is small but significant, about

1 per cent for 1° or 2° C. of mean temperature For such regular character gradients Huxley has coined the term 'cline' (see NATURE of July 30, p. 219) He suggested that such clines have in general an adaptive significance, and that the usually recognized geographical races merely represent special abstractions from them.

Prof. A. E. Trueman gave an admirable account of the views held by the majority of palæontologists as to the course of evolution It is commonly observed in fossil materials that evolutionary change, whether it be in minor matters or in fundamental structures, often proceeds in a definite direction common to many allied stocks, and that in consequence similar forms (homœomorphs), which need not be contemporaneous, are produced in such stocks

In some cases this orthogenetic or programme evolution may serve an adaptive end, but in others it seems to be unrelated to the environment and to have arisen from some restriction of the directions of variation possible to the stock

Trueman emphasized the fact that this conception of the course of evolution is merely a statement of inferred fact and does not imply any such mystical belief in a planned evolution dependent on internal factors as is often supposed to be connoted by the term 'orthogenesis'.

Dr. P. D. F. Murray, discussing "Consequential Evolution", attributed some cases of 'orthogenesis', for example, the appearance at different times in different stocks of *Titanotheres* of horns at the same points on the skull and their subsequent enlargement with time, to the effect of heterogonic growth in animals the body size of which is steadily becoming greater. The factors, genes perhaps, which determine the horns were present throughout the series, but they could not be expressed below a limiting body weight, and once expressed, develop in accordance with Huxley's formula.

Captain C Diver spoke on "Polymorphism"; he pointed out that this term is often used of such cases as those found in mimetic butterflies or in the land snails of the genus *Cepæa*, where a number of easily recognizable and discontinuous varieties of a single species occur in the same population. Such cases are necessarily restricted to those in which the variable characters are readily visible, but the condition presumably exists in many species where it affects physiological or other characters which cannot be seen directly. This apparent discontinuity between the polymorphic forms of certain species, however, grades imperceptibly into a continuous variation, and can only exist if all the polymorphic forms are in equilibrium with their environment.

Species apparently differ very greatly in their variability; in *Cepæa* there is a very wide discontinuous series of patterns and colours, occurring in parallel form in two distinct species in England and being hereditable. In the common water snail *Limnæa peregra*, there is no polymorphism in the ordinary sense, but there is a very wide variability, some of the conditions being transmitted by inheritance whilst others have no known relationship to any factors of environment or breeding. In the plant, *Plantago maritima*, we have a case in which polymorphism is combined with a considerable ecological plasticity

Mr J. Z. Young, in a witty and illuminating address, considered the broader features of the evolutionary process He pointed out that all life depends on the isolation from an environment of an individual which differs in its chemical and physical condition from it, and that this individual, which is necessarily dependent on its surroundings for all its supplies, can only be maintained by the expenditure of energy In this conception perhaps lies a meaning of the distinction between higher and lower organisms The lower organisms differ as little as possible from their environment, so that their irreducible expenditure of energy on maintenance is as small as possible, the higher inhabit more and more difficult environments, from which their own internal environment differs more and more greatly, the work which has to be done in maintaining the differences becoming progressively heavier.

It was suggested that this power of colonizing difficult ecological niches, and the increasing number of biological tricks which go with it, is a test of a high organism

The original Darwinian explanation of evolution by the "preservation of favoured races in the struggle for existence" has as its primary postulate a differential death-rate, natural selection favouring the survival—perhaps as individuals, perhaps as stocks—of those variants which best fit the circumstances in which they are living It has, in practice, proved extremely difficult to show by direct observation, on a scale sufficiently large to allow the necessary statistical treatment to be applied to the data collected, that this selective death-rate does exist.

The explanation of this difficulty has been given by the work of Prof. J. B. S Haldane He has shown that a very small selective advantage applied to one of two allelomorphic characters will, in what, from a geological point of view, is a small number of generations, produce very large effects.

In the discussion, Prof. R. A. Fisher pointed out that the accuracy obtainable in well designed and conducted field trials of crops, which afford a very close parallel, is far too little to show a selective advantage of a size which in Nature would have an enormous influence. But the possibility which now exists of predicting the proportions in which characters with a Mendelian inheritance present in a population should occur in the absence of selection, makes it possible by an analysis of large collections made from an interbreeding population to show the existence of natural selection and even to measure its intensity

Prof Fisher pointed out that polymorphic species, of the type described by Captain Diver in *Cepæa*, provide an exceptional opportunity of estimating the intensity of such selective agencies By analysis of data of populations of grouse locusts collected by Prof Nabours, he was able to show that certain dominant characters must possess a selective advantage of more than five per cent to outweigh certain genetic disadvantages which they possess, in order that they may occur in the proportion they do in the collections

The afternoon session was devoted to the more restricted field of species formation and the isolation on which it may often or always depend

Dr E B Worthington pointed out that the effects of isolation can best be studied in such limited environments as those presented by fresh waters Such areas may be geographically completely separated from one another and in such the presence of a high selection pressure by predators which may be expected to act most intensely on the not completely equilibrated intermediate stages in species formation will reduce the rate of evolution

But geographical isolation may involve and pass into the ecological isolation discussed by Dr W B Turrill He produced examples of speciation correlated with ecological isolation, and perhaps sometimes initiated by it

Dr W H Thorpe dealt with the special case of ecological isolation presented by the restriction of certain parasitic insects to one host and of other insects to one food plant The isolation so brought about may lead to the production of forms which, whilst they are morphologically almost indistinguishable, may be sterile when crossed He described experiments which showed that this restriction to definite hosts or food plants may depend on the 'conditioning' effect of the odours smelt by the insects on emergence, and that it is possible in some degree to condition such insects to quite unfamiliar odours

Perhaps the most generally important and interesting modes of isolation of certain individuals which may represent a potential new species are those which arise from internal factors genetically determined These internal factors may act in many ways they may depend on a different time of maturity of the eggs and sperms in the two groups considered, or on a mechanical inadaptation preventing mating or on a failure of the mating instinct, or in known cases in plants on an inappropriate rate of growth of the pollen tube on the stigma of the other race But all these things are most unlikely to depend on the action of a single gene, which could arise by one single mutation , they involve the interaction of a group of genes which even if it came into existence accidentally would immediately fall apart again unless it were held together by isolation

Probably the most common and certainly the most satisfactorily established modes in which such isolation may arise are those which depend on modifications in the chromosome complement of the nucleus Polyploidy may very generally lead to sterility between the parent and the new form, even when the latter is self fertile, by preventing the successful pairing of chromosomes in meiosis But such accidents as the inversion of a short length of a chromosome, or the detachment of a part of one chromosome and its subsequent adhesion to another not only lead to sterility, partial or complete, between the abnormal form and its parent, but also produce changes in the phenotype, the adult individual, even without any actual gene mutation The general position was stated by Dr C D Darlington, and some special cases were explained by Dr D G Catcheside

Finally Dr S C Harland gave a most illuminating account of the genetics of cotton He showed that wild cottons are to be found in most continents and that whilst some of them have thirteen chromosomes, others, including all the cultivated forms, possess double that number But he then went on to show that by crossing domesticated cottons with 13 chromosome species from America and Asia, the nature of the tetraploidy can be analysed, and that it has become clear that the condition has not arisen by a mere doubling but represents the addition to one another of the chromosomes of both the American and the Asiatic types A future conclusion is that plants of very similar structure may owe their characters to quite different non homologous genes Dr Harland also showed that a gene introduced by crossing into a novel environment may mutate at an exceptionally high rate

The whole discussion—although some important principles, mutation pressure for example, were not referred to—gave a very vivid picture of the present position of our knowledge of the mechanism of evolution It brought out the immense extent to which the recent very rapid advances in genetics and in cytology have removed some old stumbling blocks, and made it possible to discuss the whole subject anew and even to design experiments intended to solve problems now for the first time capable of being posed in definite terms

Post-Glacial History of the Fenland

THE Fenland Research Committee was established in 1932 under the presidency of Sir Albert C Seward and an attempt to synthesize the main results of its activities was made in a joint discussion held at Cambridge by Section C (Geology) and Section K (Botany) which may be briefly summarized as follows

The deposits in which the history of that region is recorded have been examined in drains in excavations made on specially selected sites and in natural exposures eroded by the sea along the coast These deposits consist of vast sheets of marine silts and fen peats interleaved with one another The peats are most fully developed towards the landward side where they tend to become rich in forest debris and often enclose the stumps and boles of fallen trees On the seaward side they thin away into insignificance between marine silts The general story of the region is therefore one of changes in the relative levels of land and sea resulting sometimes in periods of daily inundation by the tides sometimes in periods when the ground was covered by fen brushwood or forest

The floor upon which the deposits lie comes up to the surface around the margins of the fen country and in low hills which in prehistoric times rose up as islands in the watery waste These islands which often provided sites for human habitation became partially buried under the gradually accumulating silts and peats Excavations on one such site near Shippea Hill station have shown that successive generations left relics of their culture on the dry ground or dropped them in the adjoining fen The latter have been preserved in the peat and have furnished evidence for establishing a correlation between the physical changes and the stages in human culture

The earliest post glacial deposits found consist of peat lying along the valleys excavated in the underlying floor The composition of this peat points to the existence of woods consisting mainly of birch and pine growing on the adjoining higher ground and indicates a climate that was warm and dry About 5500 B C the climate became more moist and remained so until about 2000 B C During this time the area became occupied by sedgy fens in which peat was formed and by patches of brushwood on drier ground and was fringed by forests in which alders were common The opening of this period coincided with the dawning of the New Stone Age and the coming of Mesolithic man The later formed peat, however, yields traces of a more typically neolithic culture In this respect as well as in its composition this peat resembles that seen at the lowest spring tide on the coast between Skegness and Mablethorpe with which it may be regarded as being in part at least contemporaneous

There now intervened a time of slow subsidence during which the sea inundated much of the peat covered area and buried it under an accumulation of silts and clays which have yielded foraminifera and diatoms of brackish water type On the coast the corresponding deposits are eight to ten feet thick and are crowded with the remains of salt marsh plants a fact which shows that the subsidence that made the inundations possible proceeded very slowly Eventually it ceased and the saltmarsh gave place to fen and to conditions favourable to the formation of peat In the vicinity of Ingoldmells north of Skegness the ground became sufficiently dry for the growth of brushwood but remained sufficiently near to sea level for sea water to penetrate inland along tidal channels This combination of conditions favoured the establishment of numerous primitive salt workings The debris from these has yielded pottery fragments characteristic of the early iron age thus fixing a date about 400 B C for the complete cessation of the slow subsidence described above

Archæological evidence based upon the distribution of Bronze Age finds in the Fenland is strikingly in accord with the course of physical events outlined above During the Early Bronze Age settlement was relatively dense especially in the south With the passage of time a gradual evacuation took place which reached its culmination in the Early Iron Age There is little doubt that this movement of population was associated with the gradual extension of unfavourable conditions produced by the encroachment of high tides

The almost complete absence of later Iron Age man from both the fen and marsh land is an unexplained mystery At least so far as the latter region is concerned subsidence had ceased before the opening of the Iron Age and the level remained practically stationary until the last century of the Roman occupation for the small Roman site at Ingoldmells Point which was occupied during the first three centuries lay close to the same level as that of the salt workings Moreover as pointed out by Mr C W Phillips agriculture of a native type was carried on extensively in the Fenland during the first century and continued until the fourth There seems to be no reason therefore why Iron Age man should not have occupied the area during the preceding centuries

In the coastal exposures the saltworks debris and the Roman site are covered by marine silts and clays yielding the shells of such organisms as the cockle the oyster and *Scorbicularia* which normally live just above or below the lowest springtide levels As the tidal range is here as much as 20 ft it is evident that a rapid subsidence of that amount took place at the close of and immediately after the Roman occupation This must have rendered extensive areas uninhabitable That this was the case also in the Fenland is proved by evidence forthcoming from Welney which shows that sea floods occurred there at the end of the second century Mr Phillips in summing up the archæological evidence says In Anglo Saxon times this region was again a wilderness indicating that this state of affairs must have become worse and remained so for centuries H H S

Magnetic Alloys and Problems of Metallic Structure*

THF general character of the variation of magnetization of ferromagnetics with field is well known Different materials differ widely in their low field characteristics and in recent years there have been enormous advances in the production of materials with improved properties for particular technical applications For permanent magnet materials for example the value of $(BH)_{\max}$ on the demagnetization curve (a measure of the effectiveness being approximately inversely proportional to the volume of material required to produce a given external field in a given volume) is greater by a factor of about 5 in the modern iron nickel aluminium alloys (developed since 1931) than in tungsten steel the best permanent magnet material available twenty years ago For soft magnetic materials the improvements have been no less spectacular notably through the development of iron nickel alloys For the most part the improved materials have been the result of systematic empirical research An understanding of the factors determinative of magnetic characteristics is however clearly desirable not only from a purely scientific point of view but also from the point of view of the control and further development of technically desirable properties In this article a brief account is given of the present outlook on the general theoretical problems involved and also of recent experimental work illustrative of the manner in which the fundamental problems may be attacked

Many of the properties of ferromagnetics can be formally correlated by supposing that the elementary magnets electron spins are acted on by a quasi magnetic molecular field proportional to the intensity of magnetization This gives rise to spontaneous magnetization decreasing with increasing temperature to zero at the Curie point Ordinarily the spontaneous magnetization is unidirectional only over limited regions domains and the effect of an external field is to align the directions of magnetization of the domains Except near the Curie point the magnitude of the intrinsic magnetization is not appreciably changed so that the ordinary saturation magnetization provides a measure of the spontaneous magnetization A basic characteristic of ferromagnetics is the variation with temperature of the spontaneous magnetization The number of effective spins per atom is given by the saturation magnetization at low temperatures while from the Curie temperature an estimate can be made of the magnitude of the quantum mechanical interchange interaction which gives rise to the molecular field effects The effective spins in the ferromagnetic metals iron cobalt and nickel correspond to the number of holes in the incompletely filled electronic energy bands in the metals associated with the *d* electron states in the free atoms Owing to the manner of overlapping of bands the number of effective spins per atom will not in general be integral in accordance with observation Moreover the effect on the saturation magnetization of additions of a second element is readily interpreted at least in the simpler cases as corresponding to the filling up of the holes in the unfilled band by loosely bound electrons of the added element

---

* This article incorporates some of the material presented at a symposium in Section A (Mathematical and Physical Sciences) of the British Association at the Cambridge meeting on Magnetic Alloys and X Ray Structure held on August 19 in which the following speakers took part Prof W L Bragg Dr E C Stoner Dr A J Bradley Dr W Sucksmith, Mr D A Oliver Prof W Gerlach A general survey of the field by industrial and university workers is given in Magnetism (London Institute of Physics 1938) Recent developments in magnetic materials are comprehensively reviewed by C E Webb (*J Inst Elec Eng* 82 303 1938 Magnetization curves are fully discussed in a series of lectures collected and edited by R Becker Probleme der technischen Magnetisierungskurve (Berlin Springer 1938) For the X ray study of the iron nickel-aluminium system see A J Bradley and A Taylor *Proc Roy Soc* A 166 353 (1938)

The form of the magnetization curves depends in a complicated way on a number of secondary effects the elucidation of which is linked up with that of the status of domains The hypothesis of domains is fully confirmed by experiments on the Barkhausen effect which show that the irreversible changes of magnetization on the steep parts of the magnetization curves are essentially discontinuous the discontinuities corresponding to reversals or changes of direction through large angles of the electron spins associated with aggregates of atoms ordinarily much smaller than crystalline grains but containing as many as 10^{16} to 10^{18} atoms

In an ideal single crystal the direction of magnetization of a domain would be along one or other of the equivalent easy axes of the crystal for iron along a cube edge The effective crystalline anisotropy is however greatly modified by strain and in ordinary polycrystalline material the course of magnetization is largely conditioned by local strain inhomogeneities The strain distribution is probably largely determinative of the magnetic domain structure In the initial part of the magnetization curve the increase of magnetization may be attributed to reversible shifts of domain boundaries the shifts being greater and the initial permeability higher the smaller the strain gradients and the smaller the magnetostriction When a boundary reaches a position of maximum potential energy a comparatively large irreversible shift, corresponding to a Barkhausen discontinuity can occur the necessary field depending on the local strain amplitude The connexion with coercivity is obvious In the final stages of magnetization there is a gradual turning of the directions of magnetization of the domains towards the direction of the field

Much still remains to be done in the quantitative development of these ideas though formulæ which have been derived showing an inverse proportionality between maximum initial permeability and magnetostriction are in satisfactory agreement with experiment For high coercivity large internal strains are necessary These can be most effectively produced in heterogeneous alloys of the dispersion hardening type

The mode of experimental attack, on problems of the magnetic properties of alloys may be illustrated by reference to recent work on iron nickel aluminium permanent magnet material With the ternary alloys the most effective composition is approximately Fe_2NiAl Both quenching and very slow cooling give a material with comparatively low coercivity, high coercivity being obtained by a carefully controlled intermediate rate of cooling A first requirement in the understanding of alloy properties is a knowledge of the phases present Following earlier work a very comprehensive X ray study of the Fe Ni Al system involving the preparation and examination of nearly 150 alloys has been carried out by Bradley This enables the phase boundaries in the room temperature ternary diagram to be accurately mapped A special study was made of the Fe_2NiAl alloy At high temperatures this is a single body centred cubic phase as shown by the examination of quenched specimens On slow cooling it breaks up into two body centred phases $Fe_{20}NiAl$ (nearly pure iron) and $Fe_2Ni\,Al$ with slightly different lattice spacings On cooling at the rate appropriate for the development of maximum coercivity the segregation is incomplete and the state corresponds to the occurrence of small islands of iron rich material held in the parent lattice spacing and consequently under great strain

The magnetic properties of the alloys used by Bradley are under investigation by Sucksmith who is examining the temperature variation of the saturation magnetization An extraordinarily interesting series of curves has been obtained which will be of the greatest value for consideration in relation to the X ray data The annealed Fe_2NiAl material gives a curve which agrees closely in form with that for pure iron with the same Curie temperature and a maximum magnetization about half as great The quenched material gives a curve which at low temperatures is similar to that for Fe_3Ni diluted with aluminium (tending to a Curie point at about 400° C) but at high temperatures as annealing proceeds it approaches the curve for the annealed material

Of other recent work on these permanent magnet materials may be mentioned that of Oliver who has found that cooling in a magnetic field results in an increase of remanence of about 8 per cent The effect which is large enough to be of possible technological value may be linked up with the increase of permeability of ferro nickels under similar conditions investigated by Bozorth and Dillinger Extensive work has also been carried out on the effect of impurities and on tolerance limits of composition

Ferromagnetism is usually regarded as a somewhat specialized subject partly because ferromagnetic properties are confined to a comparatively small number of substances Many general problems of the metallic state can however be approached most effectively through the study of ferromagnetics just because a readily investigated index of the internal state is provided by the magnetic characteristics The basic magnetic properties give very direct indications of the state of the electrons in the metal and of the character of the interactions these indications can be carried over to metals generally The low field behaviour provides indications of the nature and distribution of internal strain irregularities There is no reason for supposing that domains as regions of uniform strain are peculiar to ferromagnetics they are rendered apparent only because of the associated magnetic effects The more complete study of low field properties should form a promising line of approach to the general problem of structure sensitive properties Ferromagnetic alloys combine points of immediate interest to workers in many different fields industrial and academic experimental and theoretical and it may be hoped that further co operation between them will result in rapid progress in connexion with problems not only of magnetic alloys but also of metallic structure generally E C S

Nuclear Physics

THE discussion on nuclear physics arranged to take place in Section A (Mathematical and Physical Sciences) on August 18 was introduced by Prof Niels Bohr of Copenhagen who gave an account of the new ideas in nuclear theory which have developed under his guidance during the last few years The old nuclear theory attempted to explain the interactions of fast particles with nuclei by considering the behaviour of single particles inside the nucleus rather on the same lines as in the theory of the outer electronic system This picture gave a satisfactory account ot the penetration of charged particles into light nuclei but failed to account for many phenomena in particular the large probability of capture of slow neutrons by nuclei relative to the probability of elastic scattering These difficulties have been removed by the realization that owing to the tight packing of particles within the nucleus there is a great facility of energy exchange between the particles In consequence when a particle penetrates a nucleus its energy is rapidly distributed amongst all the particles resulting in a general increase in nuclear temperature The nucleus then remains in the excited state until sufficient energy is again concentrated on one particle for evaporation or escape to occur Alternatively the state of excitation may decay by emission of radiation but owing to the high symmetry of charge distribution dipole radiation is in general unlikely and the decay period consequently long The intermediate nucleus thus exists for a period long compared with the time which would have been taken for the incident particle to traverse the system unhindered

The study of the properties of this intermediate nucleus its states of excitation and rates of decay is the point of greatest interest to day in nuclear physics Prof Bohr showed how much guidance as to its properties can be obtained from simple mechanical models Thus the system behaves in many respects like a drop of fluid and the states of excitation can be compared with the oscillations in volume and shape of a sphere under the influence of its elasticity and surface tension The experimentally established result that the distance between excited levels diminishes rapidly with increasing excitation energy suggests also that nuclear frequencies can be formed from a linear combination of a few fundamental frequencies The level distribution is therefore of a similar character to that of the quantum states of a solid body and suggestive analogies occur between the absorption of infra red radiation in solids and the absorption of high energy γ rays by nuclei In such a way the results of Prof Bothe on the wide variations in efficiency of disintegration of different elements by such rays might be explained

The energies of the stationary states can be obtained from experiments of the type described by Mr P I Dee and Prof W Bothe It is observed that many nuclear processes show resonance effects —that is they occur with maximum intensity for a particular range of energy of the incident particle This resonance is explained by the sum of the energy of the incident particle and the original nucleus coinciding with the energy of a stationary state of the compound nucleus The compound nucleus may decay either by the emission of charged particles neutrons or γ rays and in consequence the intensity of the emission of such radiations will show resonance maxima as the energy of the bombarding particle is changed The Cavendish Laboratory experiments determined the intensity and energy of the γ rays emitted when beryllium boron carbon and fluorine are bombarded by protons Resonance maxima were observed for beryllium at 350 and 670 kilovolts for boron at 180 650 850 and 950 kilovolts for the carbon isotope of mass 12 at 480 kilovolts, for the carbon isotope of mass 13 at 570 kilovolts and for fluorine at 330 470, 590, 670 860 920 kilovolts The fluorine experiments are particularly interesting in showing the closeness of the levels of ^{20}Ne when excited to 13 5 million volts A further point of interest is the breadth' of the different nuclear states Sharply defined energy states and sharp resonances occur when the lifetime of the state is long that is when the probability of decay is small In the above cases the resonance occurs because decay of the excited nucleus by particle emission is improbable The experiments determine only an upper limit to the breadth of the states owing to the spread in the energy of the incident particles (about 20 kilovolts)

Prof Bothe s experiments measured the intensity of emission of α particles neutrons and γ rays from the same intermediate nucleus He found that although some resonance levels are observed for all the radiations others occur only for one type of decay a result which introduces some difficulty for the view that the different radiations are competing methods of decay from the same nuclear state

Another method of determining energy levels of nuclei depends on observing the energies of the different groups of particles emitted when an excited nucleus returns to stability Thus when fluorine is bombarded by deuterons the compound nucleus ^{21}Ne emits four groups of α particles the most energetic group occurring in a transition to the ground state of ^{17}O and the other groups in transition to excited states of ^{17}O Thus excited states in ^{17}O at 0 83 2 95 3 77 and 4 49 million volts are found One of these was already known to be produced when oxygen is bombarded by deuterons two have been determined from experiments by Gilbert and by Bothe on the disintegration of neon by neutrons Thus different methods of formation of a nucleus show in general the same excited states

In some nuclear reactions the residual nucleus may be left in a metastable excited state in which it has only a small chance of decay by γ ray emission This may occur when the angular momentum of the metastable state differs by several units of $h/2\pi$ from that of the ground state We may then have two nuclei of the same mass and charge but with different properties Dr N Feather described cases of such isomerism' in the pair uranium Z and uranium X_2 and in ^{106}Ag In the decay of these nuclei when transition to the ground state is improbable, the nucleus usually loses its energy of excitation by transitions to one or more intermediate states so that several quanta are emitted in succession Experiments of Feather and Dunworth have shown that two quanta are emitted in succession from uranium Z and four or five in succession from the long lived isomer ^{106}Ag

Other evidence for the formation of isomeric metastable states was presented by Dr M Goldhaber Experiments carried out in collaboration with Mr R D Hill and Dr L Szilard had shown that a metastable excited state of ^{115}In designated by ^{115}In* of 4 1 hr half life time can be formed by bombarding indium with fast neutrons of as low as 2 5 m e v energy (D + D) but not noticeably with photo neutrons from radium plus beryllium which have energies of a few hundred thousand electron volts It was shown by successive chemical separations that the same radioactive isotope ^{115}In* is also formed when ^{115}Cd (2 5 days) decays emitting negative electrons ^{115}Cd was obtained by the reactions ^{116}Cd (n 2n) and ^{114}Cd (n γ) ^{115}In* (4 1 hr) can be easily studied free from ^{11} In (2 3 hr) previously reported by Cork and Thornton which is found in these experiments to have a 4 hr cadmium parent The properties of ^{115}In* are of great interest and preliminary investigations show that it emits negative electrons of 550 + 100 k v maximum energy as well as γ rays consisting of a hard component of 320 ± 50 k v energy and a soft component probably K radiation of indium It is therefore likely that ^{115}In* decays in three different ways partly into its stable isobaric neighbour ^{115}Sn with emission of β rays and partly into ^{115}In whereby the excitation energy is emitted sometimes in the form of γ rays and sometimes by internal conversion

A quite independent line of attack on excited states of nuclei was reported by Mr S Devons who has studied the scattering of α particles by helium, carbon nitrogen oxygen and fluorine The α particles scattered through a fixed angle were detected by an annular counter and the numbers recorded as a function of α particle energy In place of the smooth curves obtained in the earlier experiments where resolving power was small very well defined resonance peaks now appeared the different peaks corresponding to the different wave components by which the incident particle could be represented the energies giving the excited states of the compound nuclei

New experimental methods for the determination of the resonance levels occurring with neutron capture were reported by Dr P B Moon and Prof C D Ellis The method developed by Dr Moon and Dr C E Wynn Williams produces pulses of deuterons by modulating the input to a source of deuterons The deuterons in turn produce pulses of neutrons and these neutrons produce disintegrations at a fixed distance from the source. If then the time of the disintegration is recorded by a cathode ray oscillograph, the time taken by the neutron to travel from its source is determined and thus its velocity is found. It is therefore possible to determine with much more precision than hitherto the energies of neutrons producing particle disintegrations. This method is similar in principle to work recently reported by Alvarez in which the output of the Berkeley cyclotron was modulated

Prof. Ellis reported a simpler method of determining resonance levels in nuclei in which a lead or bismuth absorber is placed at varying points in a pile of paraffin plates separating the source from the neutron detector. Maxima in the yield of the detector are observed as the absorber position is changed By substitution of a boron absorber for the lead or bismuth, the energies of the absorption bands can be determined Thus two levels have been found for bismuth at 1 and 10 volts and a level in lead at 11–12 volts.

Dr J. D. Cockcroft and Mr. Dee described the new Cavendish Laboratory equipment for nuclear research which has been provided by the benefaction of Lord Austin. A High Voltage Laboratory has been equipped with generators for 1·2 and 2 million volts, and a vacuum tube for accelerating particles by 1·2 million volts has been in operation for a year A tube for 2 million volts has just been erected and is going through its trials satisfactorily. A cyclotron has also been built to produce deuterons of 12 million volts energy The apparatus includes a 50-ton magnet and a 100 kilowatt short-wave oscillator of accurately controlled frequency The assembly of the apparatus has just been completed, and the first indications of a 'beam' of deuterons has been obtained with the apparatus adjusted to produce 10 million-volt particles

Low Temperature Physics

FOR many years, interest in low temperature physics was largely confined to the phenomenon of superconductivity During the past four years, however, new phenomena have received attention, and at the session of Section A (Physics) on August 22 devoted to low temperature physics, comparatively little time was devoted to superconductivity. Attention was concentrated instead upon the Debye-Giauque effect, that is, the cooling of certain paramagnetic substances by adiabatic demagnetization, and upon the curious phenomenon of liquid helium II

As Dr. H. B G. Casimir pointed out in his discourse, the problems of low temperature physics fall into three categories: (1) non-magnetic insulators; (2) magnetic insulators; and (3) metals.

The phenomena to be observed in the first category are mainly extensions of those appearing at higher temperatures, such as specific heat, thermal conductivity, etc. Measurements of such phenomena agree well with theories developed by Debye, Born, Peierls and others In general, it may be said that, with one great exception (and always excepting possible future discoveries), this branch of low temperature physics is concise and definite, and that there remain only further technical measurements to be made. The great exception is liquid helium II.

The low temperature modification of liquid helium known as liquid helium II was discovered a little more than ten years ago by Onnes. Two theories have been put forward to explain its peculiar properties, neither of which has been disproved, although the weight of evidence in favour of either is not very great. What may be called the order-disorder crystalline theory, to which contributions have been made by Simon, F. London, Fröhlich, Jones and Keesom, gives a successful interpretation of the negative expansion coefficient, the high and discontinuous specific heat, and the momentum transfer which accompanies heat flow. The fact that the substance has a very small viscosity, however, makes the validity of such a crystalline theory seem doubtful.

F London has proposed alternatively that helium be treated as a degenerate Bose-Einstein gas. The discontinuity in the specific heat can be explained if certain assumptions are made concerning atomic interactions. Tiza has enlarged the theory to explain the flow and conductivity phenomena which are observed. In the Bose-Einstein picture, liquid helium II is composed of a great many 'condensed' atoms in the ground state, that is, a 'super-fluid' of no viscosity, and a few atoms in high energy states, in other words, a 'gas'. The pressure-independent capillary flow observed for the substance would then be governed by the rate of heat gain or loss in flowing in and out of a reservoir. This theory, too, has been neither proved nor disproved so far. Heat flow and fluid flow are, however, closely bound together, and are further complicated by the rapid transfer of liquid helium II in the form of surface films on every surface immersed in the liquid This means that although the experiments on the problem are quite simple and classical in type, they are invariably exceedingly difficult of true interpretation.

The second category of substances differs from the first in that the cessation of influence of thermal vibrations in the crystal lattices results in greatly enhanced magnetic effects. The phenomenon of absorbing interest is the remarkably low temperature observed on adiabatic demagnetization of paramagnetic salts. Although the effect was predicted by Debye several years before it was discovered by Giauque, many details of the process are still difficult to interpret Prof Van Vleck dwelt on several of these in his discourse on the magnetic theory of the process, and paid particular attention to the appearance of ferromagnetism in the salts at very low temperatures

Measurements on the absolute temperature scale below 1° K as determined from thermodynamic measurements on magnetically cooled salts were described by Prof. F Simon The accuracy of the measurements is quite high, but it is possible that they may be in error by 5 per cent at 0·1° K These can be compared with the temperature as determined from the susceptibility measurements, which are those actually used in any demagnetization experiments Since the temperature measured in this way depends by virtue of the demagnetizing factor on the shape of the specimen, Prof Simon has suggested that until the absolute scale is measured more exactly, temperatures measured magnetically should be reduced to those determined for a spherical specimen and should be designated by the symbol T^*

The process of adiabatic demagnetization can be most simply described as follows. At a sufficiently low temperature (1° K) the energy content of a paramagnetic salt, such as iron ammonium alum, is mainly composed of the disorder of the magnetic ions. Isothermal magnetization to, say, 10,000 gauss, lowers the entropy of the salt at that temperature by reducing the disorder of the ions. Adiabatic demagnetization then does not alter the entropy, and hence the temperature is reduced to the neighbourhood of 0·05° K. The disturbing effects are the interactions of the magnetic ions with themselves and with the lattice. The second can be reduced by choosing a substance such as cæsium titanium alum, and the first by iron ammonium alum in which the ions form a small part of a very large molecule, and it can be somewhat further reduced by dilution of the salt so that the ions are still more separated from each other One obtains an optimum value in this way, since too much dilution lowers the specific heat of the ions in relation to that of the rest of the substance

A possible lower limit to temperatures obtained in this way might be put at 0·001° K. If we consider, however, the possible future use of the nuclear magnetic moments as a means of cooling, a two-stage process using a paramagnetic salt to cool a metal with a suitable nuclear moment which in turn is adiabatically demagnetized, it is possible that even lower temperatures might be realized

Up to the present time, comparatively little has been done in the way of using magnetic cooling to reduce the temperature of other substances. Now that the absolute temperature scale is fairly well established, however, and we know that within a few seconds at most after demagnetization the lattice of the salt is in thermal equilibrium with the ions, we can expect much more investigation of other physical properties in the temperature range from 0·05° to 1° K

In the third category of substances, that of metals, the theory built up by Sommerfeld, Bloch, Peierls, and others fails to explain the sudden appearance of electrical superconductivity in certain metals at low temperatures, although it does allow the resistance to approach zero at the absolute zero in an ideally pure metal In spite of the great amount of data available on superconductivity, it remains almost completely mysterious Many theories have been submitted to account for it but have failed, although a very promising phenomenological theory by F. London appears to be quite satisfactory within the scope of its application It is almost certain that one cannot consider superconductivity as a one-electron problem, and that it must instead be treated as concerned with electron groups.

Considered thermodynamically, however, certain features, such as the 'threshold curve', that is, the temperature variation of the critical field for destruction of superconductivity, do admit of successful analysis, as has been shown by Gorter and Casimir. But the true nature of superconductivity still eludes us Here again, although the experiments are in general simple, the difficulties of exact interpretation are very great. In spite of the fact that an enormous mass of data on superconductivity is at hand, a good deal of it is rather haphazard, as is natural when one is dealing with a mysterious phenomenon. Many more experiments must be carefully made under conditions of known metal purity in order that the mass of apparently disconnected small effects may be either proved spurious or fitted into the picture.

J. F. ALLEN.

Repercussions of Synthetic Organic Chemistry on Biology and Medicine

THE recent discussion* on Repercussions of Synthetic Organic Chemistry on Biology and Medicine held on August 23 under the auspices of Section B (Chemistry) of the British Association at the Cambridge meeting directs attention to one of the most striking features of modern organic chemistry namely its increasing preoccupation with naturally occurring substances of biological importance The reasons for this change of heart on the part of the chemist long divorced from biology are too varied to be dealt with here but there can be little doubt that the development of microchemical technique has done much to render it possible In a discussion such as that at Cambridge it was impossible to cover more than a fraction of the investigations in this field but from the subjects actually chosen by the various speakers it is possible to obtain a general view of the ways in which organic chemistry is affecting biology and medicine

Intensive research in many centres on the nature of the various sex hormones has led to results of great interest All these compounds belong to that group of natural products containing the ring skeleton of the sterols Three classes of sex hormones are now well defined the œstrone group the androsterone testosterone group and the progesterone group Several natural compounds of the first group are known these have primarily the power to produce in female animals the changes in the reproductive tract characteristic of the time of ovulation (œstrogenic activity) The same is true of the second group the members of which can stimulate the atrophic accessory organs and secondary sexual characters of castrated animals (androgenic activity) but in the third group progesterone is the only known naturally occurring substance which produces to any marked degree progestational changes in the female reproductive tract

Synthetic closely related substances are known having similar biological activity to hormones of all three groups Synthesis in the sterol sex hormone group of course refers to partial synthesis from other natural substances since the fundamental ring system of the sterols has not yet been synthesized The testing of a large number of synthetic substances related to the natural hormones has brought out a variety of points of great interest to chemists and biologists alike It has been found for example that only derivatives of androstane are androgenic and that the degree of activity depends largely on the nature of the substituents in positions 3 5 and 17 in the nucleus (I) and on the stereochemical configuration of the compounds Here as in other groups of physiologically active substances stereoisomers differ markedly in activity

The structural differences between members of all three classes of sex hormones are relatively small and biological investigations carried out with the natural and synthetic substances have brought to light the surprising fact that multiple activity is common in the sex hormone group Thus it has been established that in the above series of androgenic substances many show weak œstrogenic and some weak progesterone like activity

Work on the isolation of sex hormones from natural sources too has shown that male and female animals differ in the proportion of the various sex hormones rather than in their nature The very close relationship between the various physiologically active steroids has been even further emphasized by the recent series of investigations on the hormones of the adrenal cortex Efforts to isolate the cortical hormone capable of maintaining life in adrenalectomized animals have led to the isolation from adrenal cortex of at least five different compounds possessing this property in varying degree and it is probable that others will yet be isolated All these substances are sterol derivatives resembling the sex hormones in structure Deoxycorticosterone the most active substance so far obtained differs from progesterone only by having an additional hydroxyl group and even shows some progesterone like activity

In fields other than hormone chemistry too considerable advances have been made in the determination of the structural features necessary for the exhibition of a particular effect by a given compound Following on the isolation and identification of the hydrocarbons in coal tar which have the power of causing cancer a large number of polycyclic hydrocarbons have been synthesized and examined for carcinogenic properties Of these the most potent and best investigated are derivatives of 1 2 benzanthracene (II) In mono alkyl derivatives of this hydrocarbon carcinogenic power is possessed in increasing degree by those bearing the substituent in positions 6 9 5 and 10 respectively In the case of poly alkyl derivatives substituents present in these positions appear to reinforce one another, yielding some of the most potent carcinogenic agents at present known. To this group of 1 : 2-benzanthracene derivatives belong 3 : 4-benzpyrene, a substance undoubtedly responsible for skin cancer among coal tar workers, and methyl cholanthrene. The carcinogenic activity of the latter substance is noteworthy as it can be prepared in the laboratory from cholesterol and the bile acids, substances normally present in the body. There is some structural resemblance between many carcinogenic substances and members of the sterol-sex-hormone group, and the continuance of such investigations may bring us closer to a knowledge of the cause of cancer.

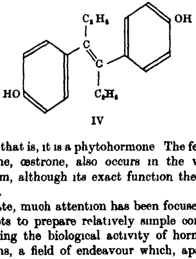
III



IV

In the field of vitamin chemistry, advances have been very rapid in recent years and a number of vitamins have been synthesized and have become available for medical and biological purposes In the case of the antineuritic factor (vitamin B_1, aneurin), discussed at Cambridge, the availability of the synthetic vitamin has led to the discovery of many hitherto unsuspected uses in clinical practice, while the work at present being carried out on the part played by it in carbohydrate metabolism is giving us a clearer insight into its function in animal organisms. Many investigations have also been made with the view of ascertaining the structural details necessary for vitamin activity. In the case of aneurin (III), the investigations so far indicate a high degree of structural specificity, for apart from alteration in the nature and position of the alkyl group on the pyrimidine ring, little structural change in the molecule is possible without complete loss of activity. It would appear that less variation in structure is possible than in the case of the sex hormones A high degree of structural specificity seems to be a feature of many vitamins

A point brought into prominence by the work on aneurin is that our present classification of certain natural substances as 'vitamins' and of others as 'hormones' appears to be rather arbitrary, and recent work shows that a distinction between the two groups cannot always be upheld. For example, biological experiments have shown that aneurin, while it functions as a vitamin in animals, appears to be essential to plants as a root-growth factor, that is, it is a phytohormone The female sex hormone, œstrone, also occurs in the vegetable kingdom, although its exact function there is not known.

Of late, much attention has been focused on the attempts to prepare relatively simple compounds possessing the biological activity of hormones or vitamins, a field of endeavour which, apart from theoretical importance, has an obvious practical interest in medicine In experiments on the synthesis of œstrogens, striking results have already been obtained By following out a scheme of simplification of the œstrone molecule, substances have been arrived at, the œstrogenic activity of which, astonishingly enough, far outstrips that of the natural hormone. To mention a particular case, the compound 4 : 4′-dihydroxy-α · β-diethylstilbene (IV), also known as stilbœstrol, has an œstrogenic power about ten times as great as that of œstrone The compound at first sight appears to be wholly unlike the sex hormones in structure, but, theoretically at least, its conversion into a substance with a chrysene skeleton might be readily achieved by a double ring closure Whether or not this possibility has a bearing on its biological activity it is too early to say In any event this imitation of the effect of a hormone by a series of synthetic substances foreign to the body opens up a field with great possibilities Medical and biological investigation of the properties of stilbœstrol are as yet incomplete but present indications are that it has all the properties of an œstrogenic hormone It would thus seem to be an artificial hormone like substance of a type entirely different from say synthalin which although lowering the blood sugar like insulin nevertheless does so in an entirely different manner from the hormone

Generally speaking there appear to be two types of investigation carried on by the organic chemist which have a direct effect on biology and medicine One of these deals with the isolation structural identification and synthesis of substances responsible for particular biological effects and the determination of the structural features in these compounds essential to activity The other is concerned with the synthesis of simple compounds which will exhibit the same biological action as natural hormones and vitamins Bearing in mind the old lock and key theory of physiological action we might regard the first type as a search for Nature s keys and the second as an effort to prepare skeleton keys to serve similar ends

Physical Chemistry of Clay

IT is a remarkable tribute to the liberal outlook of Section B (Chemistry) of the British Association that the four principal contributors to the discussion on clays held on August 22 at Cambridge were physicists The basic principles governing the chemistry of the silicates are as Prof W L Bragg explained clearly revealed in their crystal structure Every silicon atom is surrounded by four oxygen atoms in tetrahedral arrangement In olivine the (SiO_4) groups are separate while in silica and the feldspars each oxygen is a component of two tetrahedra Between these extremes we find the pyroxenes and amphiboles in which the tetrahedra are linked by common oxygens into parallel chains and minerals like mica in which the tetrahedra are linked into parallel sheets

Kaolinite is the best crystallized clay and it appears reasonably certain from the work of Gruner and others that it contains sheets of linked tetrahedra Three of the four oxygens of each tetrahedron are shared and these oxygens form the base of the sheet The middle layer contains the unshared oxygens plus half their number of hydroxyls and the top layer consists entirely of hydroxyls Between the middle and top layers are aluminium atoms surrounded in octohedral symmetry by four hydroxyls and two oxygens The structure may be represented thus

$$O_6\ Si_4\ O_4OH\ Al_4\ (OH)_6$$

Montmorillonite the principal clay mineral in bentonite and fullers earth gives rather poor X ray powder diagrams and single crystals large enough to be examined in detail have not yet been obtained for X ray examination Dr G Nagelschmidt explained that the mica-like structure proposed by Hoffmann Endel and Wilm is probably correct but it cannot be regarded as established as the X ray evidence is insufficient Other tests can however be applied The ideal composition as exhibited by pyrophyllite is

$$O_6\ Si_4\ O_4OH\ Al_4\ O_4OH\ Si_4\ O_6$$

Several authors have reported the loss in weight in the neighbourhood of 500° C to be less than the 4 per cent that would bring the clay to $Si_4Al_2O_{11}$ but some recent measurements on fractionated bentonite are in agreement with this prediction A critical study of the technique of dehydration is desirable The chemical composition of montmorillonite is rather variable but the silicon content never exceeds that of pyrophyllite In view of the established structure of mica it is reasonable to suppose that enough aluminium is present replacing silicon to complete the layers of linked tetrahedra and enough iron and magnesium are present in the central layer to replace aluminium The substitutions of aluminium for silicon and magnesium for aluminium cause the lattice sheets to be negatively charged and cations must be present to preserve electrical neutrality In a number of cases that have been worked out in detail, this structure satisfactorily accounts for the cations found A few cases appear not to fit and these require closer examination

A striking characteristic of montmorillonite is that the spacing of successive lattice sheets varies reversibly according to the relative humidity the intervening water layer varying from nothing to four molecules deep The balancing cations are held in these water layers only by electrostatic forces and are readily exchangeable for others carrying an equal charge The thickness of the water layer at a given relative humidity depends on the kind of cation that is present.

The fact that the number of exchangeable ions held by a clay depends upon the hydrogen ion concentration of the clay shows, as Dr. R. K Schofield pointed out, that clay particles carry other electric charges besides those arising from isomorphous replacements. There are evidently 'spots' on the particles which are charged or uncharged according to the reaction of the medium. They are of two kinds : acidic spots, where negative charges can develop through the dissociation of hydrogen ions, and basic spots, where positive charges can develop through the combination of hydrogen ions. The process in the case of the acidic spots is probably

$$\equiv \mathrm{Si} - \mathrm{OH} \rightleftarrows \equiv \mathrm{Si} - \overset{-}{\mathrm{O}} + \mathrm{H}^+$$

the silicon atoms being those situated at the edges of the silicon-oxygen layer The chemical nature of the basic spots is uncertain. They are not found in the clay minerals so far identified, but are frequent in the common clays The equilibrium is possibly

$$- \overset{+}{\mathrm{Al}} - \mathrm{OH} \rightleftarrows - \mathrm{Al} = \mathrm{O} + \mathrm{H}^+$$

and may be due to an overcrowding in the octohedral layers. In certain clays the number of basic groups exceeds that of the negative charges due to isomorphous replacements. These exhibit well-defined iso-electric points.

The forces which hold the successive lattice sheets together appear to be of three kinds. In the case of pyrophyllite and talc, both the faces of the sheets consist of oxygens shared between silicons, and only very weak residual fields are available to hold one sheet to the next. In kaolinite one face consists of oxygen and the other of hydroxyls. The layers are stacked with the oxygen layer of one sheet facing the hydroxyl layer of the next In this case, Prof. J D. Bernal explained that 'hydroxyl bonds' must here be regarded as providing the principal linkages. When the sheets are charged, the balancing ions act as ties. In mica the attractive force is strong enough to keep water out, but in montmorillonite, with fewer isomorphous replacements, water at high relative humidities can partially separate the sheets The development of thixotropy in clay suspensions within a certain range of salt concentration is doubtless connected in some way with this effect, but Prof E. K Rideal mentioned cases where this behaviour seemed to be due to a small amount of the clay that had dissolved. Observations on the behaviour of clays towards water were made by Dr E. W. Russell and Mr. H H Macey.

Problems of Crop Production

IN devoting a session on August 22 to problems of crop production, Section M (Agriculture) was dealing with one broad aspect of a wider question—the place of science in the advancement of British agriculture. More than simple efficiency of production is implied by advancement. It means also the development and extension of farming to the fullest economic degree and, if demonstrably necessary in the national interest, to a degree beyond the limit set by financial economics. Now advancement in the industry at large, like success on the individual farm, is dependent first on policy and next on technical farming efficiency. Science can promote efficiency both by providing new knowledge and by helping farmers to make the best use of existing knowledge ; that is, by research and by education.

It must have been in the minds of those who listened to this discussion to ask whether science's contribution must be limited to technical efficiency or whether it might not have a part in making national agricultural policy. Views put forward at an earlier session, when employment on the land was discussed, plainly inclined to the idea that in applying itself to agriculture, science must take national policy as it finds it and be content to work within its limitations But ever since the end of the Great War, protagonists, some scientific, some lay, have claimed for science a strong share in government, including the shaping of policy It may be regretted that, when discussing the part of science in agricultural advancement, the Section did not boldly debate the question what part, if any, science could take in shaping agricultural policy

The title under which this discussion took place is significant—the practical problems of crop production. In conferences connected with science and agriculture it is usual to deal only with current experimental work So much is this the case that discussion as to what are the main problems of crop production very rarely occurs Yet it is the great problems of farming practice which agricultural science is under obligation to try to solve. In its efforts it constantly has to take up special problems in pure science But the final objective must always be to help the agricultural industry.

The plan of discussion classified the problems of crop production under husbandry practices, crop varieties, and damage by pests and diseases The question of crop varieties may seem almost wholly for the plant breeder In fact, however, it creates producer problems wherever crops are grown under even moderately intensive conditions The basic consideration is which variety of the crop concerned will pay best With modifications in special cases, yield first and next quality of produce, determine remunerativeness Many farmers still cling pathetically to the hope of finding in some new variety a means of getting higher yields without greater effort on their own part In undeveloped agricultures it may be fairly easy for the breeder to satisfy this hope But with crops already highly improved, like British cereals, the plant breeder can do no more than produce varieties which will give higher yields—*in a way that the older varieties cannot*—under a higher level of husbandry That is, the breeder can help the farmer to raise the level of output, but cannot solve for him the problem of raising or maintaining soil fertility

The old question of the importance of high botanical uniformity of type among the plants in a field has aroused a new, more critical, interest Among its many farming and genetic aspects, influence on quality of produce attracts most attention It seems evident, indeed, that the whole question of quality ought to be re examined The farmer may be expected to concern himself about quality, whether in choosing the variety or in husbandry practices only in measure as he is paid for quality But what is this measure ? Discussion revealed a feeling that modern household taste and modern processing technique are so developing as to divest quality of some of its importance in many crop products and further, that to guide the farmer and to ensure reasonable price recognition of quality, experimentally determined standards will have to be specified Farmer and agricultural scientist cannot alone deal with this matter , consuming interests have a part to play and, in some cases, an urgent problem—to find out more clearly what they themselves require in quality of crop products

The variety problem, from a plant breeding point of view, brought up a question which, though never under direct discussion, gloomily intruded itself more than once upon Section M—the question of Britain's agricultural policy To produce a new variety by hybridizing may take fully fifteen years Who is to say whether in fifteen years' time mangolds, swedes, turnips, kales, beans, peas will have dropped to the small acreage their decline of the past years suggests ? Yet on this turns the wisdom of undertaking expensive breeding work on them Their future place depends on the extent to which meat and milk are to be produced from arable land or from grass , and this question is perhaps as big as any in the future of our agricultural policy It involves cereals, too, in the matter both of grain and of straw, and manifestly bears fundamentally on grasses and clovers It is thus a prime determiner of the major practical problems not only of breeding but also of husbandry, both crop and animal

In husbandry practices the problems of urgency are recognized to be not new questions but old ones made important by new resources, such as mechanical power , by new conditions, such as world surplus in staples like wheat and sugar , by economic pressure under which land drainage has fallen into decay and cash crops have displaced livestock on arable land, in some minds to the permanent detriment of soil fertility

The readiest example of such problems is cultivations They include ploughing, cultivating, sub soiling, harrowing, hoeing, rolling Whether their source of power be tractor, horse or the bullock or hand tool of tropical countries, the modern cultivator has begun to ask himself questions about them What, exactly, is their effect on soil and crop and, thus, to what extent are they necessary ? Local custom once told a farmer how often to plough for a root crop and whether to plough fleet, medium or deep He asks now whether anything is gained by cultivations beyond the minimum necessary to make a seed bed bury large rubbish and kill weeds The tea planter in India or Ceylon, the sugar beet grower in Britain and his rival in tropical sugar cane countries, and indeed the grower of almost any crop anywhere, recognizes here a pressing question

Maintenance of soil fertility is a problem of no less wide application but much greater gravity Its crux is commonly held to be soil organic matter, and discussion showed sign of return to the view that the old, uncompromising rotational farming is the only sure foundation for maintaining soil fertility Land drainage also came under review This is overshadowed by the sorry fact that in present conditions owners and tenants cannot afford to restore or replace the old land drains which have been vital to British farming since about 1840–60 Tractor power has made a new contribution to mole draining, but there remains the great difficulty that we have but crude ideas as to the influence of depth, distance apart, and orientation of drains It was held that the final solution of these practical problems could only be found in a full knowledge of water movement in various soils

Past experiment on cultivations and on the control of fertility by fertilizers, manures and farming systems, reveals a conception of problems not acceptable from the point of view taken in this discussion It was formerly the object of experiment to find out the effect of any treatment on the immediately following crop and on that alone Now the practical problem is widely accepted to be the cumulative effect of these methods and treatments on the soil and on the yield of all the crops throughout a rotation

Science cannot solve the exact problems which confront the farmer It has to ascertain the scientific questions by which the practical problem is made up and to deal with these In the case of cultivations and maintenance of fertility the simplest kind of investigation would be field trials to measure the effect of various treatments on crop yield Such measurements would not give understanding or point the way to further progress Here the questions for science are how each cultivation or other treatment influences the soil and directly or through the soil the crop These influences can only be measured by the plant itself That is a developmental study must be made to determine how at each point in plant life treatment influences growth and development and thus ultimately final yield To make developmental studies under field conditions is exceedingly difficult Plant physiology could do a service to agricultural experimentation by devising measures or indexes of growth and development suitable for field use

In dealing with pests and diseases of crops the natural tendency towards vigorous offensive may overcome business common sense Prominence was given in the discussion to the need for careful estimates of extent and nature of damage to crops To find a method of control or prevention is not the full solution of the practical problem how much can profitably be spent in applying the method remains in many cases a problem also

Of plant parasites—insect fungus or other—the types most to be dreaded are those capable of lingering in the soil for several years Examples are take all (*Ophiobolus graminis*) of wheat and eelworm of potatoes or sugar beet No direct means of destruction is known in any of these cases though indirect methods sometimes biologically fascinating are coming within view Safety lies at present in avoidance in a policy of temperance In fact what was said from the husbandry point of view in the discussion about the merits of uncompromising rotation was effectively reinforced by considerations of disease The apparently steady increase of take all foot root and similar diseases in cereals in many parts of the world was declared to arise from the tendency to lessen the interval between one corn crop and the next Correspondingly the tendency and the temptation to grow successive crops of early potatoes or sugar beet has already created a problem of geographic extent and of gravity which few realize Restriction on freedom of cropping—in the past a matter of statute law and leases—has its severest importance as a matter of biologic law and herein lie perhaps the greatest problems of plant pathology

Present Aspects of Plant Virus Research

THE discussion on present aspects of plant virus research held on August 23 by Section K (Botany) at Cambridge covered the whole range of plant virus work from the properties of purified virus proteins to the propagation of healthy potato stocks

Recent work by Dr Kenneth M Smith and Mr W D MacClement on the natural modes of dissemination of plant viruses has shown that the ld idea of an insect vector as essential for the pread of a virus from plant to plant is true only o a limited extent Some of the best known viruses apparently have no insect vector and ther means of dissemination must exist *Solanum* virus I spreads by the contact of diseased and healthy leaves especially when agitated by wind *Solanum* virus II which is found in the roots of apparently healthy glasshouse plants and does not normally enter the aerial organs is disseminated in at least two ways It has been isolated from the sludge in glasshouse tanks and may be introduced to the soil during watering Experiments with plants grown in air proof chambers have shown that it also spreads from pot to pot by air borne particles of infected plant material This virus and *Nicotiana* virus I have both been recovered from the air one hour after being atomized into it When the former has been atomized into the air of an air proof chamber the plants grown in it under sterile conditions have become infected while those in an adjacent chamber which was not atomized remained healthy *Lycopersicum* virus 4 could be recovered from the air only for 5–10 minutes after atomizing while *Solanum* virus I could not be recovered from the air at all

The problem of multiplication of adequate stocks of healthy potatoes has occupied Dr R N Salaman s attention for many years At present only a third of the potato acreage in England is planted with approximately clean seed and this leads to a reduction in actual yield as compared with possible of some two tons per acre for the remaining two thirds Future policy in regard to the potato crop should aim at obtaining maximum tonnage per acre by the use of healthy seed and by the suppression of ground keepers always a fertile source of virus infection

In the fight against virus disease the use of carrier varieties is to be deprecated There is little hope of obtaining in the near future either genetic or acquired immunity to the serious virus diseases leaf roll and leaf drop streak and only drastic reorganization of the potato seed trade offers hope of ameliorating the situation A scheme was outlined by which really virus free seed available at Cambridge should be multiplied first in moist wind swept areas on the west coasts of Scotland and Ireland then grown in the present good seed growing districts and finally distributed to the ware producing regions of England This scheme would include perpetual replenishment of the seed stocks from healthy sources and would afford a prospect of ultimately eliminating loss due to virus disease

The methods of virus purification originally applied to tobacco mosaic have now been extended by Mr F C Bawden and his co workers to potato virus *X* tomato bushy stunt and cucumber viruses 3 and 4 In principle they consist in heating the infective sap to 60° C (which coagulates most of the normal plant proteins) and precipitating the virus protein from the supernatant by addition of ammonium sulphate Final elimination of host proteins is accomplished by digestion with proteolytic enzymes which do not attack the virus protein All the above viruses yield nucleoproteins with very uniform analyses Final proof that these proteins are pure viruses is impossible to obtain at present but heterogeneity of the purified products cannot be shown by ultracentrifugation or other means The slight loss of infective power shown by some of them is attributed to aggregation of particles Thus in the host plant tobacco mosaic probably exists in the form of approximately spherical particles In the purified protein these aggregate to form long rods imparting to the solutions optical properties such as anisotropy of flow commonly associated with crystalline structure This virus does not crystallize *in vitro* but the virus of tomato bushy stunt does so in the form of rhombic dodecahedra

The origin of potato viruses in Great Britain is probably to be sought in their introduction from South America with the ancestors of the domestic potato In a study of the virus content of fifty nine cultivated potato varieties from Puño South Peru Dr R W G Dennis has discovered evidence of the presence of viruses resembling British *X F G B C* and leaf roll Viruses *A* and *Y* have not so far been found in South American material but there exists in Peruvian potatoes a number of viruses differing from any known in Furope Only eleven of the varieties studied were found to be healthy Investigation of the photo periodic reactions of South Peruvian potatoes shows that there is no reason on that ground for the conclusion that the domestic potato and its viruses could not have been derived from the plateau region of Peru and Bolivia

Horizons in Animal Production

THE discussion on animal production in Section M (Agriculture) of the British Association at Cambridge on August 23 had one excellent result it demonstrated very clearly indeed the inseparableness of the three main constituents—animal husbandry (the feeding and management of livestock) animal breeding and disease control Gone it would seem are the days when the animal nutritionist claimed that feeding was more important than breeding or the geneticist that breeding was more important than feeding or the animal pathologist that control of disease was a laboratory problem divorced alike from heredity and husbandry This is not to say that specialists in each of the three fields have so far been wasting their time for there is plenty of evidence to show that in explaining and improving existing practices they have done very necessary work The animal geneticist for example although he has been unable to direct the emergence of strikingly new and improved types of livestock has been able to interpret the mechanisms of heredity to define the prerequisites for successful in breeding and to examine the significance of mutations

There is too the welcome sign that no longer is a specialist in one field prone to dismiss an unsolved problem by deciding that the solution lies in another field the time has come when further advance can be hoped for only by co operation and by studying the animal as a creature living in a given environment and in relation to the demands made in it by society

The separation of the problems of animal production into those requiring immediate attention and those that can be dealt with only on a long term basis can easily be made Into the first category come measures for disease control and measures for increasing efficiency of production through improvements in feeding and management already established but not generally adopted Prof R Rae believes that in recent agricultural legislation (the Agricultural Act and the Livestock Industry Act both of 1937) there exists the machinery for immediate improvement in both spheres if the interpretation of the Acts is courageous and intelligent This is especially the case where the organization of producers for marketing purposes provides also the organization for stimulating improvement in the quality of the produce For example without the Milk Marketing Board the guaranteed extra payment for milk from herds free from tuberculosis would be impossible This payment is already acting as a considerable incentive to the eradication of tuberculosis As Dr J Hammond pointed out it is much wiser to pay producers to improve their business in this way than as in the past to allow them to rear diseased stock and to earn compensation by slaughtering it The question of food supplies for animals in the event of war is also a problem of the present in this connexion the newer methods of making silage from our grassland merit attention

The problem of disseminating the results of research is to day as important as any problem requiring research The gap between the enlightened practice of the few and the mediocre practice of the many worries all who observe it It is admittedly a problem affecting the whole of farming practice and about it Prof R G Stapledon had much to say An improvement in rural education is of first importance so that farm labour may be recruited from the ranks of the best rather than from those who are left when the brightest have migrated to town jobs The rural schools recently started in Cambridgeshire and elsewhere aim to solve this problem and if those leaving school could begin a definite apprenticeship on the land (as suggested by Prof Rae) the quality of farm labour could be raised to meet the more specialized requirements which it must now fulfil

For the present there is hope of improving the efficiency of production by the spread of quite simple schemes (of which the food recording schemes for pigs and dairy cows are examples) that provide very valuable yard sticks The producer is not given an abstract counsel of perfection he has his enterprise—his herd of pigs or milking cows—carefully costed for him and with the help of a skilled supervisor is able to compare his ability as a manager of livestock with that of his neighbours and to discover directions for improvements Producers grouped into marketing organizations with monopolistic powers are under a moral obligation to the State to make such schemes general

The material in a paper on animal diseases by Dr E L Taylor provides a convenient bridge for crossing from the problems of immediate importance to those of the future It illustrates too the nature of the new approach In the past there has been a tendency to study all diseases in a pathological laboratory but Dr Taylor defined disease as a flaw in the environment Dealing chiefly with the worm parasites (which cause enormous loss and are of special importance to the sheep industry) he showed the close relation between the health of the animal its environment and its tolerance of parasites For example the age of the animal and its plane of nutrition are important factors young growing sheep do not have the resistance of mature sheep and under nourished mature sheep quickly lose their tolerance A sheep may pass as many as 200 000 worm eggs and be in normal health if its constitution is reduced (for example by poor nutrition) the number may increase to 9 000 000 per day The circle is vicious pastures become infested and all sheep suffer While in rare cases specific medicines may effect cures for such a disease there is the much simpler and cheaper cure of good husbandry Improved pastures and rotational grazing provide a better plane of nutrition and another species of livestock—cattle for example not susceptible to sheep parasites can be employed to clear up sheep grazings

In human medicine the part played by improved housing sanitation and nutrition in eradicating disease is now generally recognized In animal production it is certain that improved methods of feeding and management will yield comparable results The hope is real that the new State veterinary service will provide veterinary husbandmen rather than veterinary pathologists

The futures of animal nutrition and animal genetics are going to be closely related to the prosecution of anatomical and physiological research Almost all applied problems can be resolved into terms of the anatomy and physiology of relative growth of reproduction and of endocrinology It may seem a far cry from these to society's demand for small succulent joints of meat rashers of bacon with the right proportion of muscle to fat, eggs of satisfactory weight and milk of better quality or to the desire of the producer to breed and feed livestock that will meet these demands and yet remain fit and profitable but the connexion exists In the field of meat production Dr Hammond has shown the great possibilities of altering the proportions and quality of the carcass by varying the shape of the growth curve Even in closely in bred animals of a pure breed an astonishing flexibility in their response to varying planes of nutrition has been demonstrated This exploitation of the animal as it grows promises great advances over the old methods of measurement of "live-weight gain per unit of food consumed". Prof. F A E. Crew maintains that it is this flexibility (or "degree of modifiability" as he calls it) which must be established for our existing breeds and types of livestock before the geneticist can play his full part

The importance of further research in the physiology of reproduction is emphasized by the incidence of sterility in livestock, much of which is certainly not pathological, and by the economic need of maintaining and increasing fertility. In this field the use of sex hormones is bound to play a large part—Prof. Crew's forecast of the syringe replacing the seasons is apt. The work at Reading on the lactogenic hormones indicates great potentialities in the sphere of milk-production

The discovery of a new technique is usually of fundamental importance, and that of artificial insemination is no exception The improvement of the quality of livestock in Great Britain is greatly hampered by the small size of the breeding-units. For example, one half of the quantity of 'wholesale' milk dealt with by the Milk Marketing Board comes from herds containing ten cows or less The owners of such small herds cannot afford to buy a sire of adequate merit, and in fact the majority use non-pedigree animals. The result is that much of the home-bred stock is unsatisfactory and new stock has to be purchased This practice, besides being most inefficient, often is responsible for the introduction of disease. Through the development of artificial insemination, there is the prospect that the small herd may benefit from the use of sires at present confined to the larger herds, where their services are far from being fully exploited

The evolution of breeds of livestock existing to-day has been directed by breeders working closely with a constantly improving environment and to a definite purpose There is every indication that the process can be continued and accelerated, and that more can participate in it

Prontosil

Messrs Bayer Products, Ltd, Africa House, Kingsway, London, W C 2, have issued a booklet surveying the chemotherapy of 'Prontosil', the trade name of three varieties of the sulphonamide series of drugs Prontosil has been found to possess active properties against human infections caused by the bacterial streptococci, and to be of great service in the treatment of puerperal fever and certain forms of blood poisoning It also appears to be of service in the treatment of meningitis caused by the meningococcus and in some other infections The booklet gives a useful summary of the experimental work that has been done on the physiological action of Prontosil, and of its use in treatment A bibliography of some two hundred of the more important references is appended Although a trade production, this booklet gives a fair presentation on the subject of Prontosil'

Appointments in the Colonial Service

The following appointments and promotions have recently been made in the Colonial Service G W Anderson, to be agricultural officer, Kenya, G K G Campbell, to be agricultural officer, Nigeria, L J S Littlejohn, to be botanist and plant pathologist, Cyprus, S M McCombe, to be agricultural officer, Uganda, C W R McCreary, to be agricultural officer, Nyasaland, P R Stephenson, to be entomologist, Uganda, J Barker, to be nutritional investigator, Nyasaland, E Collins, to be Government analyst, Mauritius, J P Glasgow, to be field officer, Tsetse Research Department, Tanganyika Territory, R L Stafford, to be assistant meteorologist, Nigeria, H E B Williams, to be sleeping sickness control officer, Nigeria, J A Fawdry, inspector of mines, Tanganyika Territory, to be chief inspector of mines, Northern Rhodesia, W G Beaton, veterinary research officer, to be senior veterinary officer, Nigeria, N Clarke, veterinary officer, to be senior veterinary officer, Nigeria, R Dunwoody, veterinary officer, to be senior veterinary officer, Nigeria, A B Ackland, chief clerk, Agricultural Department, to be produce inspector, Agricultural Department, Fiji, P W Briggs, agricultural officer and ginnery inspector, Tanganyika Territory, to be agricultural officer and ginnery inspector, Uganda, R W Hamilton, chief inspector of antiquities, to be director of antiquities Palestine, W O Harvey, game ranger, Tanganyika Territory, to be deputy game warden, Selangor and Negri Sembilan, Federated Malay States, H L Manning, assistant agricultural officer, British Honduras, to be plant breeder in charge of the Cotton Experiment Station, St Vincent (under the Empire Cotton Growing Corporation)

Announcements

As we go to press, confirmation has reached us of an announcement made a few days ago that Dr S B Nicholson, using the 100-inch reflector at Pasadena, has discovered two new satellites of Jupiter The objects are extremely faint, the estimated magnitude being 19 No particulars are yet available as to their orbits

Prof Florence Barbara Seibert, assistant professor of biochemistry, Henry Phipps Institute of the University of Pennsylvania, Philadelphia, has received the Trudeau Medal in recognition of her research on the chemistry of protein molecules derived from the tubercle bacillus Prof Seibert is the first woman to receive the Trudeau Medal

Dr Hermann Fink, professor of the biochemistry and technology of fermentation in the University of Basle, has been awarded the Scheele Medal of the Stockholm Chemical Society

Dr Hans Herensky of Johannesburg has been given the Leibnitz Gold Medal of the Prussian Academy of Sciences and Dr Georg von Bokesy of Budapest the Leibnitz Silver Medal

Prof H Frieser, of Dresden, has become editor of the *Zeitschrift fur wissenschaftliche Photographie, Photophysik und Photochemie* published by Joh Ambr Barth, of Leipzig, previously edited by him with Prof Schaum, of Giessen

A Neo Hippocratic Congress will be held in Marseilles on September 29 under the presidency of Dr Cornil, dean of the faculty of medicine Further information may be obtained from Dr Martiny, 10 rue Alfred Roll, Paris

An International Balneological Association has recently been founded in Budapest The first meeting will be held in Germany this year, the next in France in 1940, and the third in Italy in 1942, during the world exhibition

We have received vol 9 of 'Studies from the Connaught Laboratories, University of Toronto" (The University of Toronto Press, 1938), edited by the director, Dr J G FitzGerald In this volume are bound together reprints of fifty papers, published in different journals during 1937 from the Connaught Laboratories and University of Toronto The papers cover a wide range of subjects, from public health and pathology to biochemistry and physiology A brief inspection of the volume gives a good idea of the activities of the Toronto School A list of the papers included is given at the beginning of the volume, but there is no subject or author index, which would add to its value as a work of reference

Erratum In the letter entitled 'Control of Insects by Methallyl Chloride', by Dr C J Briejèr, in Nature of June 18, p 1099, the third line under the formula "Mixtures of its vapour with air are not explosive in concentrations of 105–339 gm per cub m", should read, "Mixtures of its vapour with air are explosive in concentrations of 105–339 gm per cub m."

NOTES ON POINTS IN SOME OF THIS WEEK S LETTERS APPEAR ON P 540

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

The Law of Error

DR J NEYMAN, in his review[1] of Karl Pearson s Grammar of Science , which was republished on my suggestion, quotes a passage from my recent paper[2] on the law of errors as a remarkable illustration of the confusion of the perceptual and the conceptual spheres of thought The whole of my work on probability is based on the recognition of the distinction between description and inference, the neglect of which is responsible for much confusion in current statistical and physical theory Inference, in my opinion, begins at an even earlier stage than Pearson states in the ' Grammar In the passage quoted it should be clear that I am speaking wholly in the inferential sphere An actual set of observations is necessarily discrete and cannot be described by any continuous law of error But it may provide means of saying which of several continuous laws is the more probable on the data

Dr Neyman says that observations are irrelevant to the truth of a mathematical theorem I agree But a theorem that rests on the postulate that an error is the resultant of many comparable and independent components is not wholly mathematical, and can apply only to errors that do satisfy those conditions, and the observed distribution of errors is relevant to whether those conditions are satisfied For this reason I think that many elaborate experimental investigations to test for example, the binomial and χ^2 distributions, are misinterpreted They do not test whether the distributions would hold in the conditions postulated in their proofs, they test whether those conditions have been satisfied in the design of the experiment But in the case of the mathematical 'proof' of the normal law of error, it is not shown, or even true, that the law holds for all possible errors *even if the conditions postulated in the proof are satisfied*

On the other hand, the law of error, whatever it is, is a description of a distribution of chance, not of any set of observational facts It is the exception, not the rule, for a set of observations to be sufficiently numerous even to distinguish between the normal and triangular distributions of chance, and if any law is asserted from some set that is sufficiently numerous, and then the method of combining the data that it implies is applied to another set that is not sufficiently numerous, inductive inference is used So also is the hypothesis that the actual discrete observations have been derived from *some* continuous law of chance, and that the discreteness is due only to the fact that the number of observations is finite

Considering that I have been insisting on the distinction between description and inference for nearly twenty years, I think that I might have been spared the accusation of confusing them

I think that the time has come also for a protest against the statement that continues to be made in statistical writings that a prior probability is a frequency So far as I am aware, the principle of inverse probability was stated by Bayes eighty years before the first statements of any frequency definition, by Leslie Ellis and Cournot A frequency definition was certainly not used by Bayes or Laplace, and Wrinch and I showed in 1919 that it would not suffice as a basis even for direct methods What is done in direct methods is that an inference from a hypothesis to the observations (which can be made on the hypothesis that chances exist, without the circumlocution of a frequency definition to provide an unsatisfactory justification) is converted at the end by a verbal argument into an inference from the observations to the hypothesis, what the principle of inverse probability does is to replace this verbal argument by a symbolic statement To convert either into a prediction of a long run frequency involves a use of Bernoulli s theorem, the conditions for the applicability of which need very careful statement, which they scarcely ever receive

Effects of Be-D Radiations upon *Vicia Faba*

THE retarding action of neutron rays upon the roots of wheat seedlings has been reported by R E Zirkle, P C Aebersold and E R Dempster[1], and recently by R E Zirkle and I Lampe[2], but the daily growth of individual seedlings after irradiation has not been reported yet In the present experiments, the lengths of individual roots of *Vicia Faba*, which were exposed to radiations produced by bombarding a beryllium target with 2 8 Mev deuterons from the cyclotron of this laboratory, were measured day by day after the exposure

Three days before irradiation, the seeds were submerged in distilled water for one day and then planted in sawdust saturated with sterilized tap water, in a dark thermostat at 30° C, where they were allowed to remain exactly for two days before irradiation Then, only those individuals the primary roots of which were from 15 mm to 25 mm long were selected for the experiments For irradiation, two of these seedlings were planted in a small glass box filled with sawdust, and were placed in the dark observation chamber of the cyclotron, where they were exposed to the beryllium deuteron radiation for one hour at a distance of 6 5 cm from the beryllium target, the deuteron current being 10 microamperes During the same period two more seedlings, planted in another glass box, were placed for control in a dark chamber which was kept distant from the cyclotron After the exposure, the irradiated seedlings together with the controls were put on a wooden plate, floating on tap water in a two litre glass beaker, and their roots were placed separately in glass tubes, which were hanging down from the plate into the water The beaker was kept in the dark thermostat at 30° C, and the lengths of the main roots were measured every 24 hours after the exposure

The average growths in length of the main roots of fifty irradiated seedlings during the intervals of 24, 48, 72 and 96 hours respectively after the beginning of irradiation, are given in the second row (R) of the accompanying table, and σ is the standard error of mean For comparison, the corresponding data of fifty non irradiated controls are given in the third row (C) of the same table From the standard errors obtained, we can see a clear retardation of growth even in 24 hours after irradiation The ratio R/C decreases with the lapse of time after the exposure, and becomes 46 per cent after a period of 92 hours Further, we found that side roots never appeared in the irradiated specimens within 4 days, while in controls 94 per cent of the individuals have sprouted lateral roots by this time

Period after radiation	24 hr	48 hr	72 hr	96 hr
R (length in mm)	16 7 (σ = 0 8)	22 7 (σ = 1 0)	24 5 (σ 1 2)	24 7 (σ = 1 0)
C (length in mm)	23 7 (σ = 0 8)	39 5 (σ = 1 0)	48 9 (σ 1 3)	52 9 (σ = 1 4)
R/C (per cent)	70 4	5 4	50 3	46 9

While we were carrying out these experiments, retarding actions of X rays upon the main root of the same species were determined, in exactly the same manner, by Misses M Sudô and S Imai in the laboratory of one of us (M N) According to their experiments, the ratio R/C at an interval of 4 days after one hour irradiation with X rays (160 kv, 0 5 mm Cu, 0 5 mm Al) for calculated doses of 200 r, 300 r and 400 r are 59, 52 and 40 per cent respectively The intensity of our beryllium deuteron radiations under the present conditions thus corresponds to about 6 r/min of X rays when measured by the retarding action in 4 days after the exposure on the main root of *Vicia Faba*

In conclusion, our thanks are due to Prof S Nishikawa, Dr Y Nishina and other members of the Nishikawa laboratory as well as of this laboratory for their kind suggestions and valuable assistance, especially in connexion with the operation of the cyclotron We wish to thank the Japan Wireless Telegraph Company for the electromagnet and other equipment used for the cyclotron, and the Mitsui Ho-onkwai Foundation, Tokyo Electric Light Company and Tôyogû Tercentenary Memorial Endowment for financial support

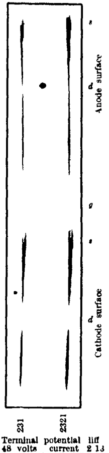
Pure Stark Effect observed in Metallic Arcs

IT has been generally accepted that in an arc the observation of the pure Stark effect can scarcely be expected, as the drop in potential in the immediate neighbourhood of the electrodes is of the order of the ionization potential of the gas and the dark space is so thin (10^{-8} cm or less) that its detection is extremely difficult, the uncontrollable fluctuation of the arc and the effects due to pressure and inter ionic fields may give rise to further complexities, which manifest themselves in the anomalous behaviour (diffuse broadening or shift) of spectral lines



Terminal potential diff 48 volts current 2 13 amp arc length 3 5 mm

In spite of these expectations we have now succeeded, by proper choice of arcing conditions in observing the pure Stark effect for a number of lines of iron copper silver, nickel and aluminium, most of which belong to the spark type An enlarged reproduction of a small segment of the spectrogram of silver is given in the accompanying illustration

Important points to be noted, as the results of the present investigation are (1) that in a steady metallic arc there can exist at least two regions *s*, where the field intensity is so great that the pure Stark effect can be observed namely at a certain distance (c 1 5 mm) from the lower (positive or negative) electrode and in the immediate neighbourhood of the upper electrode, (2) that there are fairly large drops of potential occurring in *two* steps at *each* electrode, the indication of which is the appearance of the spark lines and so there are three points along the arc where the field intensity becomes a minimum—at two regions *d* about 0 8 mm distant from the electrodes and at the centre *g* of the arc, (3) that, when the pressure is reduced, no essential change is produced in the potential distribution along the arc, (4) that as the length of the arc is varied, the length of the region *g* changes linearly with it, while the behaviour of the lines near the electrodes remains the same

An Application of a New Limitation in Physical Theory

IN attempts to understand the relation between the quantum theory and the theories of relativity and electro magnetism, a certain limitation, applicable to the motion of a particle of electromagnetic mass m_0 and of charge e, is brought to light It appears that the expression ($m_0c^2d\tau - e/c\Sigma\varphi_m dx^m$) can assume only those values which are multiples of Planck's constant[1].

$d\tau$ is an element of proper time associated with the track of the particle, dx^m is a component of displacement and φ_m is a component of electromagnetic potential An interesting result is obtained if this be applied to an electron in an electrostatic field of potential Ne/r This is the case with an electron in an atomic orbit where N is the number of the atom The above condition then implies $(m_0c^2\sqrt{1-\beta^2} - Ne^2/r)\, dt \nless h$ where $\beta = v/c$ v being the velocity of the particle, and where account is taken of the fact that the nuclear and electronic charges are of opposite sign If we consider the case of the K level of an atom and make use of Sommerfeld s value for Ne^2/r which may be regarded as a sufficient approximation we obtain $m_0c^2\,(\sqrt{1-\beta^2} - \beta^2/\sqrt{1\ \ \beta^2})\, dt \nless h$ In this case $\beta = N\alpha$ where α is the fine structure constant $2\pi e^2/hc$ We note that as β approaches the value $1/\sqrt{2}$ the factor of dt approaches zero very rapidly and the limitation states that the least possible value of dt is very large We interpret this as an indication of the breakdown of the description of the charge as a particle in motion This gives a clue to the nature of the limitation It provides us at each point of space and time with a criterion for the dynamical description of an electric charge

In this particular example the limitation is interpreted to mean that the K level does not exist when $\beta = N\alpha \gg 1/\sqrt{2}$

The condition appears to be similar to a condition of stability, the K ring at a certain point becoming completely unstable

The value of N which results from this equation is very close to 97, and we conclude that atoms with numbers up to 96 may possess a complete set of energy levels beginning with the K level Beyond this, K levels do not exist and nuclei of a larger number would possess energy layers beginning at a higher level[2]

The condition $\beta \ngtr 1/\sqrt{2}$ can be expressed by stating that electrons in atomic orbits have de Broglie wave lengths greater than h/m_0c It is interesting to note in conclusion that in the example considered we find another relation involving the fine structure constant to add to the considerable number already known

Ultra-Violet Band System of Silicon Monotelluride

FOLLOWING up the recent observations of ultraviolet band systems of SiS[1] and SiSe[2] in heavy current discharges through silica tubes containing aluminium sulphide and aluminium selenide respectively, I have now applied an analogous method for the development of the corresponding system of SiTe In this case, a 2 5 amp A C discharge has been passed through a powdered mixture of aluminium and tellurium in a silica tube The system lies between λ 3307 and λ 3831, having its 0 → 0 band at λ 3496 4

As guides to the identification of the SiTe system there are not only the progressive changes in the system origins and vibrational coefficients of SiO, SiS and SiSe, but also the data for the corresponding system, B ← X, of SnS, which has the same number of electrons (66) as SiTe There is, indeed, a remarkable similarity between the expressions for these two systems, just as there is between those for the corresponding systems of the lighter isoelectronic pair, GeS and SiSe (48 electrons), thus

$$\left.\begin{aligned}\nu_{\text{GeS}} &= 32889\ 5+(375\ 0u' -1\ 51u'^2)-(575\ 8u''-1\ 80u''^2)\\ \nu_{\text{SiSe}} &= 32448\ 7+(404\ 3u' -3\ 24u'^2)-(580\ 0u''-1\ 78u''^2)\end{aligned}\right\}$$

$$\left.\begin{aligned}\nu_{\text{SnS}} &= 28337\ 9+(331\ 9u' -1\ 25u'^2)-(487\ 7u''-1\ 34u''^2)\\ \nu_{\text{SiTe}} &\ \ \ 28665\ 9+(333\ 4u' -0\ 54u'^2\ \ 0\ 05u'^3)\ \ (480\ 7u''\ \ 1\ 30u''^2)\end{aligned}\right\}$$

where, as usual, u stands for $v + \frac{1}{2}$

The values of $I_M I_X/E_e$ and ω_e/ω_e'' for SiTe are 20 6 and 0 694 respectively which are of the same orders of magnitude as those previously found for SiS and SiSe The ratio (ω_e of SiTe)/(ω_e of SiSe) takes the values 0 824 and 0 829 for the excited and ground states respectively As expected, these are greater than those for (ω_e of SiSe)/(ω_e of SiS) namely, 0 790 and 0 774 respectively, which, again are greater than those for (ω_e of SiS)/(ω_e of SiO), namely, 0 602 and 0 604 respectively A similar change is found[3] in the corresponding ratios of coefficients in the case of PbTe PbSe, PbS and PbO

Band Spectrum of Helium

WHEN helium at a pressure of about 25 mm of mercury is excited in such a way as to produce the line spectrum and the band spectrum in comparable intensity, McCallum and Wills[1] find that the band spectrum persists much longer than the line spectrum after the excitation is removed They show a spectrogram of the discharge, taken 1/600 sec after the discharge had been interrupted, in which the line spectrum has disappeared while the band spectrum is still of approximately the same intensity as that from the discharge before interruption

From this persistence of the band spectrum McCallum and Wills infer that either the helium molecules formed in the discharge have a life of the order of 1/600 sec or, more probably, they are formed after interruption of the discharge by the collision of a metastable atom with a neutral atom

That the latter inference is correct is shown by the recent work of Arnot and M'Ewen[2], who have investigated the formation of helium molecules by the balanced space charge method, and have shown that the helium molecule is formed in the ionized state by the attachment of a metastable atom in the $1s2s$, ^3S state of 19 77 volts energy to a normal atom This paper was published after McCallum and Wills's letter was communicated

Fundamental Physical Structure

THE suggestion by Dr. Drysdale, in NATURE of August 13, that by resorting to the experiments and equations of Ampère relating to the forces between current-carrying conductors, magnetism may be eliminated from fundamental physical concepts, reminds me that in the course of conversation with the late Sir Horace Lamb some years ago, he remarked that it would greatly simplify mathematical treatment if we could dispense with the duality of electricity and magnetism and concentrate on one of them, as Ampère appeared to have done. The hint was the more impressive because Sir Horace, in his 'Hydrodynamics", had set forth the vortex theory so convincingly.

What Dr. Drysdale now does is to substitute the force corresponding to the product of charge and velocity of a proton or electron, for Ampère's current-element force, thus eliminating the magnetic link. It is difficult to dissociate permeability from what Dr. Drysdale designates 'magnetic considerations", but presumably it would take its place as a general variable in the concept.

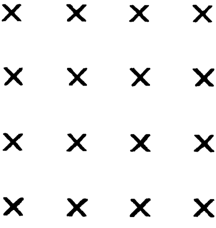
A Binocular Illusion

I WAS much interested in Sir Richard Paget's letter in NATURE of July 9, as I have observed the converse effect, in which a 'suspended image' may be seen *behind* the pattern viewed.

The effect may be obtained by drawing a simple pattern (for example, of crosses, as in the enclosed sketch) enlarged so as to give a suitable interval between the elements; this is rather less than the distance between the eyes (in my case, two inches for an eye interval of two and a half inches). The pattern is held at a suitable distance—about twelve inches—and the eyes relaxed; having persuaded the blurred images to coincide so that one element is superposed on its neighbour's image, the eyes are focused *without* losing this superposition, that is, without turning them inwards to their original position. The illusion of a magnified image behind the object is assisted if the eyes are permitted to move over the pattern or blinked, or if the pattern is moved slowly towards and away from the observer.



A chessboard held diagonally is a suitable pattern, but the illusion is much more striking with an object such as wire netting, and I have found a window pane of frosted glass with a pattern of stellate clear patches (at the appropriate interval) very effective indeed; the most favourable conditions, however, require a little practice and patience.

The optics of this phenomenon are of course similar to those of Sir Richard's version. The eyes are focused for an object at a certain distance, but the angle subtended by their respective lines of sight is appropriate to an object at a greater distance.

Antarctica and Glacial Ages

As geologist to the British Graham Land Expedition, I should like to direct attention to certain misstatements which appear in Prof. E. W. MacBride's recent article[1] concerning the geological discoveries which our expedition made in the Antarctic.

Prof. MacBride states: "The part [of Antarctica] so far principally studied is that directly south of South America, in which lies the inlet known as the Ross Sea." A glance at the map will show that the Ross Sea is some 100°–120° of longitude west of South America. Our expedition was working in what is commonly referred to as the West Antarctic, which is south of South America but very many miles from the Ross Sea. Further, Prof. MacBride states that we collected from the Beardmore glacier erratic rocks 'of the Gondwana age, with coal seams carrying characteristic fern plants". He probably has in mind the Permo-Carboniferous plant remains which were collected by Captain Scott's polar party from the region of the Beardmore Glacier, and which were described by Sir Albert Seward. The Beardmore Glacier is nearly 2,000 miles from the region we visited. The only plant bearing deposits we found were from the eastern shore of Alexander the First Land, and are probably Middle Jurassic but certainly not Permo-Carboniferous or 'Gondwana' in age. As a result of Prof. MacBride's misstatements it is difficult to understand what geographical relation he assumes the Antarctic Permo-Carboniferous deposits bear to the presumed continent of Gondwanaland. Consequently it is doubtful how far the arguments which he bases on their distribution may be regarded as relevant.

Prof. MacBride states that Antarctica entirely escaped the "Gondwana ice age", but since no rocks of Permo-Carboniferous or Gondwana age have yet been found in West Antarctica (which, it should be remembered, is markedly dissimilar from the region round the Ross Sea both as regards the geological formations that occur and their tectonic structure), no certain conclusions can be drawn as to the climate of this part of the continent in 'Gondwana' times.

In recent years many lines of evidence have accumulated to suggest that during past geological ages various parts of the earth's crust drifted relative to one another and to the axis of the earth. The widespread distribution of a characteristic Permo-Carboniferous flora throughout many lands, which are now widely separated, is of particular significance. There is also evidence to show, as Prof. MacBride points out, that drifting may still be going on at the present day, at all events in certain parts of the world. It is hard to escape the conclusion that continental drift is one important contributory cause of the Permo Carboniferous and other pre Pleistocene glacial epochs, but to claim, as Prof MacBride does, that drift into high latitudes affords a complete explanation of all glacial phenomena previous to the Pleistocene is surely to propose a too facile solution for a highly complicated group of problems which further information can alone clarify

W L S FLEMING

Trinity Hall,
Cambridge
July 28

NATURE 142 97 99 (July 16 1938)

IN answer to the criticisms of the Rev W L S Fleming I have frankly to admit two foolish mistakes in nomenclature For Ross Sea read Weddell Sea,' and the height of land from which the Beardmore Glacier takes its origin is of course a few projecting peaks which are *not* Erebus and Terror

The mistakes in nomenclature leave my argument quite unaffected indeed since then I have measured on *The Times* map the actual breadth of the ice shelf If, as Dr Stephenson assures me, the Beardmore Glacier is 200 miles long, the breadth of ice shelf to be added is 1 200 miles This gives 1 400 miles as the length of the ice flow and nothing in the Pleistocene ice flows approached this

With regard to the fossils from the rocks beneath the ice sheet, I thought that all knowledge of these was gathered from the erratics which Scott brought back I am delighted to learn that Jurassic strata are exposed in one place and that these show no signs of glaciation It is of course conceivable that, while one part of Gondwanaland escaped Gondwana glaciation, another part did not do so—but this is not a likely supposition

My conception of the Gondwana ice age is as follows In Permo Carboniferous times there was one huge southern continent, lying in temperate regions to the north and east of the South Pole In this continent there was a characteristic flora which enables portions of it to be recognized wherever they are

In Permo Carboniferous times it drifted southward over the pole At that time Australia and Antarctica lay at its northern edge As the drift continued, both Australia and Antarctica broke off and remained in the temperate zone The rest of the continent as it reached the pole underwent severe glaciation, after which in Cretaceous times it broke into three great fragments, namely, South America, South Africa, the Deccan of India, in all of which traces of this ice age can be seen Sir Thomas Holland has said that these traces can be detected in portions of the north of India, so far did the drift go on At a later period the same drift affected Antarctica and led, as I said, to its present condition

Mr Fleming, while agreeing generally with the theory of continental drift, says that it is a rash thing to make it account for all the ice ages It certainly does not account for the Pleistocene ice age, as I said But besides the Pleistocene there are only two well authenticated ice ages in the history of the earth, the Pre Cambrian and the Gondwana So far as I can find out, there are no traces of the Pre Cambrian ice age in the southern hemisphere Beds supposed to belong to this ice age in India have been recently shown to be relics of the Gondwana ice-age

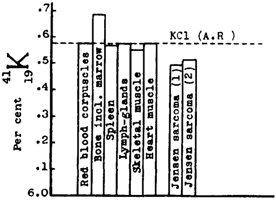
Isotopic Constitution of Potassium in Normal and Tumour Tissue

WITH the idea that the isotopic constitution of potassium contained in tumour tissue might be somewhat different from that present in normal tissue comparative investigations in this field have been undertaken The abundance ratio $^{39}_{19}K/^{41}_{19}K$, and thereby, practically, the concentration of the heavy isotope $^{41}_{19}K$, was estimated in potassium present in the ashes of various kinds of normal and tumour tissue, the measurements being carried out by means of a mass spectrograph previously described in detail[1,2]

A selection of the results so far obtained is illustrated in the accompanying figure, showing the percentage of $^{41}_{19}K$ in potassium contained in Jensen rat sarcoma and in some normal rat tissues of mesodermal and mesochymal origin, including red blood corpuscles It will be seen that the content of $^{41}_{19}K$ in potassium present in red blood corpuscles as well as in spleen, lymph glands and heart muscle, was the same as, or very close to, that in mineral potassium contained in ordinary potassium chloride (A R) In contrast the $^{41}_{19}K$ content in potassium present in bone, including marrow, showed an increase by about 1 7 per cent This deviation was probably due to the marrow alone and confirmed similar results previously obtained with marrow from other animal species[2] The $^{41}_{19}K$ content in potassium from skeletal muscle showed a doubtful decrease of about 0 4 per cent Ashes for these determinations were prepared from mixed tissues taken from an equal number of males and females The average animal weight, corresponding to each tissue, was between 210 gm and 225 gm



CONCENTRATION OF $^{41}_{19}K$ IN POTASSIUM CONTAINED IN JENSEN RAT SARCOMA AND SOME NORMAL RAT TISSUES

In comparison with the above results it was found that the relative $^{41}_{19}K$ content in Jensen rat sarcoma was distinctly low Two samples of ash from tumours obtained by subcutaneous inoculation are here considered The tumours constituting sample (1) had an average weight of about 15 gm and were taken, 18 days after inoculation, from animals having an average weight similar to those considered above, the tumours constituting sample (2) had an average weight of about 14 gm and were taken, 14 days after inoculation, from animals having a much lower average weight The potassium in sample (1) contained about 1 3 per cent and that in sample (2) about 1 0 per cent less $^{41}_{19}$K than mineral potassium Both living and necrotic parts of tumour were utilized in the preparation of these samples, but two other samples prepared from only living parts showed approximately the same percentage

Similar slight deviations were obtained in potassium from mouse sarcoma 37 S and from some forms of human cancer tissue , so far no corresponding normal tissue has been taken for comparison, except human bone marrow, which gave results similar to rat bone marrow

Detailed accounts of our investigations will appear elsewhere

Active Group of Papain

FROM their work on the active group of papain Bersin[1] and Purr[2] concluded that the SH group was essential for the hydrolysis of gelatin by the enzyme the activity disappearing with the oxidation of the SH to the SS form

We have already shown that the papaya latex is rich in SH compounds (about 2 per cent) and that about a tenth of it is glutathione[3] This observation led us to the examination of the activation of papain

An aqueous extract of the fresh latex, previously extracted with ether, was treated with hydrogen peroxide to oxidize all the SH to the SS as shown by the nitroprusside test, and then precipitated with alcohol, washed with absolute alcohol and dried in vacuum This preparation, while being completely inactive towards peptone, retained its capacity to hydrolyse gelatin Its gelatinase activity was comparable to that of the preparation activated by hydrogen cyanide or glutathione Its optimum *p*H was in the neighbourhood of 3 far below the value (4 6–5 0) reported in the literature for papain The reaction mixture before and after incubation did not answer the nitroprusside test The results obtained are tabulated below

(250 mgm gelatin or peptone + 250 mgm of SS prepn in 20 c c of buffered solution *p*H 3 Temp 38° C Time of incubation 20 hr The activity is measured by the increase in formol titration of 2 c c of the reaction mixture against 0 1 *N* caustic soda)

		Gelatin	Peptone
1	SS preparation in citrate buffer	0 25	0 00
2	in acetate buffer	0 27	0 01
3	+hydrogen cyanide	0 38	0 30
4	+glutathione	0 48	0 46
5	+maleic acid	0 26	0 00
6	+iodoacetic acid	0 00	0 00

Maleic acid, which has recently been shown to inhibit the activity of enzymes the activity of which depends on the presence of the SH group[4], is without effect on the gelatinase activity of the preparation Iodoacetic acid inhibits the activity irreversibly

These results indicate that for the gelatinase activity of papain the SH group is not necessary ; other groups which react irreversibly with iodoacetic acid appear to be essential At the same time, it is evident that the SH group is essential for 'peptonase' activity.

We have also got evidence that the papain hydrolysis of the protein takes place in two definite stages, first to peptone and then to simpler amino acids , the activation mechanism being specific for the two stages

Excretion from Leguminous Root Nodules

IN previous communications[1 2 3] I have reported my inability to detect appreciable excretion of nitrogenous substances from root nodules of leguminous plants and thus to confirm the results obtained by Virtanen During the past summer further trials have been carried out with soya bean (4 varieties) pea (5 varieties) and broad bean Three rooting media have been employed namely (*a*) a coarse quartz sand composed of particles of diameter mostly in the region of 0 5 mm (*b*) a fine quartz sand of particles diameter 0 1 0 3 mm and (*c*) a very fine quarry sand of particles 0 1 mm and less (*b*) appears to be very similar to the sand used by Virtanen Open and closed containers have been used while the tests for excretion consisted of analysis of rooting medium and of barley plants grown in association with the legumes

Satisfactory growth and fixation were shown by the legumes, but in no instance was evidence of excretion obtained The pea varieties included Torstai and Concordia inoculated with bacillus strain *HX*, combinations which in Virtanen s experiments gave vigorous excretion I have repeated Virtanen s arrangements and conditions so far as is practicable and yet have obtained very different results It is clear that apart from the possible influence of factors such as identity of legume bacterial strain and adsorptive capacity of rooting medium some other factor has a controlling effect on excretion Wilson and his collaborators[4 5], recently reached a similar conclusion from their Wisconsin experiments and advanced evidence that excretion depends on the maintenance of a certain relation between rate of photosynthesis and of fixation, and for this reason is liable to be affected by light intensity and temperature These factors were *not* subject to close control in my experiments The soya beans were grown in a lean to greenhouse partly shaded by trees, with a day temperature of 65–75° F The other legumes were placed outside on dry days in a position where they received a maximum of six hours sunshine daily No difference in excretion has emerged in these experiments between soya bean and the so called cool weather legumes, negative results having been obtained in all cases

The Mexican Loggerhead Turtle in Europe

THE Mexican loggerhead turtle, *Colpochelys kempi* Garman, is distinguished from *Caretta caretta* (Linné) by its colour, in possessing four enlarged infra marginals instead of three on each side, and its smaller size A native of the Gulf of Mexico and adjacent waters, it is so localized that few if any European museums possess specimens Hence its appearance off the west coast of Ireland is of unusual interest

Two specimens so obtained in 1928 and 1934 are now in the National Museum at Dublin and are No 92—1928 and No 108—1934 respectively The straight carapace length of the former is 256 mm, of the latter 245 mm These will be dealt with more fully by me in the *Irish Naturalists Journal*

The presence of *Colpochelys kempi* in these waters suggests that the common *Caretta caretta* which appears off Ireland is also derived from American waters, and not from the neighbouring south European seas This opinion is further supported by a *Caretta caretta* in the Whitby Museum with the label Washed aboard ss *Ethelfreda* North Atlantic 1926

It is thus very probable that the presence of *Caretta caretta* (Linné) in European waters is mainly if not entirely due to currents, for no definite breeding grounds exist on the European coast as on the American side of the Atlantic

The possibilities of sea turtles as current indicators would thus appear to be considerable, and it is to be hoped that their importance in this respect will receive due recognition

Visual Image Produced by a Photoflash Bulb

A LUMINOUS visual image, very closely resembling some 'ball lightning' observed at high altitudes, may be produced by the firing, without warning, of a photoflash bulb just beyond the limit of an observer s normal field of vision

The optical illusion produced will be described by the observer as a greenish or reddish ball that wandered into his field of vision from the side, became smaller and changed colour near its centre (right in front) and finally faded and vanished No two persons will give identical reports

From the foregoing, it is suggested that certain (not all) reports of ball lightning' are actually descriptions of an optical illusion (probably a sort of after image) produced by a brilliant lightning flash somewhere just outside the observer's visual field

RONALD L IVES

1129 13th Street
Boulder, Colorado

Points from Foregoing Letters

COMMENTING on Dr Neyman's remarks in a recent review of Pearson s Grammar of Science , Dr Harold Jeffreys states that the law of errors is a description of a distribution of chance, not of observational facts It does not hold for all possible errors, even if the conditions postulated in the proof are satisfied He also points out that the principle of 'inverse probability' was stated long before any 'frequency definition

An appreciable retardation in the growth of the roots of broad bean seedlings, after exposure in a cyclotron chamber to radiations from a beryllium target bombarded with a deuteron current of 10 microamperes, is reported by Prof M Nakaidzumi and K Murati

An enlarged reproduction of the lines 2317 and 2321 A in the arc spectrum of silver, obtained under special arcing conditions, and showing splitting due to the electric field (Stark effect) is submitted by Dr J Huruiti and Prof T Hori Their investigation throws light on the distribution of the potential drop and field intensity within the arc

By applying a new limitation, arising from quantum relativity relations, to an electron moving orbitally in an electrostatic field, Dr H T Flint obtains a condition of stability which indicates that in atoms with atomic numbers larger than 96 the *K* level cannot exist

R F Barrow reports the observation and vibrational analysis of the ultra violet band system of SiTe corresponding to the SiSe, SiS and SiO systems already described by him and Dr W Jevons

A binocular illusion in which a regular pattern, by suitable adjusting, appears enlarged and suspended behind the actual pattern, is described by J D Morton

The Rev W L S Fleming corrects certain points to which Prof MacBride referred in his article on "Antarctica and Glacial Ages ' concerning the British Graham Land Expedition s geological discoveries No rocks of Gondwana ' age have yet been found in West Antarctica and there is no evidence as to what climate this part of the world experienced during the ' Gondwana ice age Existing evidence does not justify the conclusion that continental drift affords a complete explanation of all pre Pleistocene glacial phenomena Prof E W MacBride admits two errors in nomenclature, but claims that by substituting "Weddell Sea" for ' Ross Sea ', the argument is unaffected

The isotopic constitution of potassium contained in tumour tissue and normal tissue, mainly from the rat, has been studied by Dr A Lasnitzki and Dr A K Brewer Distinct, although slight, deviations from the norm were obtained with the potassium present in tumour tissue and bone marrow The percentage of $^{41}_{19}$K was decreased in the former case, increased in the latter

C V Ganapathy and B N Sastri state that if the sulphydril group SH of the enzyme papain is oxidized by hydrogen peroxide, the enzyme loses its power to act upon peptone, but retains its hydrolysing power on gelatine, indicating that for gelatinase activity the SH group is not necessary

Further experiments with sand cultures of soya bean, pea and broad bean carried out by Dr G Bond fail to confirm appreciable excretion of nitrogenous substances from these root nodules

Research Items

Standards of Living in Africa

THE problem of raising the standard of living in native Africa with special reference to the contribution to its solution which may be made by the anthropologist has been the subject of consideration by Dr Margaret Read in the light of recent experience among the Ngoni of Nyasaland (International Institute of African Languages and Cultures *Mem* 16 1938 Oxford University Press Pp 56 Price 1s) Apart from the difficulty of a quantitative evaluation of the present standard of living in a community existing partly on a subsistence economy partly on a money economy the problem of raising the standard calls for a deeper analysis probing to the values which govern present consumption and the incentives which determine present production—in other words study of institutions Study of Ngoni institutions shows that in the past economic activities were dependent upon and organized through the social system of the people In the changes due to cultural contact it is the economic life which has been altered most radically The native authorities though deprived of most of their traditional means of wealth are expected to promote schemes of native welfare more or less on European lines The fundamental difficulty is that economic progress cannot be dissociated from political and social development if either are to be maintained In a brief survey of cattle keeping agriculture and the paramount chief's market it is shown that there is no automatic reaction to environment nor is there any automatic or uniform reaction to culture change introduced by Europeans The Ngoni have resisted the suggestion of a commercial attitude towards cattle Their organization of agriculture and distribution of its proceeds have collapsed owing chiefly to forces outside their control, but in the paramount chief's market he has created deliberately a new form of activity which though based on an old traditional relationship, meets some of the new needs of the people The variation in the reactions of the people to efforts to improve their welfare suggests the usefulness of careful preliminary inquiry before introducing innovations such as farm schools and co operative societies Economic progress must be in line with political development if either are to achieve stability and permanence

Manuring of Soft Fruits

Two interesting investigations on the manuring of soft fruits have recently been recorded (*J Pom and Hort Sci*, 16, 1938) The first, by T Wallace, concerns black currants, and the second, by T Wallace and V G Vaidya, refers to strawberries The black currants, variety Baldwin, were given a series of manurial treatments consisting of farmyard manure, no manure, complete artificials, and complete artificials less nitrogen, phosphorus and potassium respectively The order of crop yields was the same as that for vigour, namely, farmyard manure, complete artificials, omit nitrogen, omit phosphorus, omit potassium Severe attacks of *Pseudopeziza Ribis* occurred each year potash deficiency appears to have decreased susceptibility to this fungus whilst deficiencies of nitrogen and potassium tended to increase it The strawberries, variety Royal Sovereign were given three dung treatments complete organic manures containing shoddy and dried blood respectively as sources of nitrogen dried blood without potash complete artificials and no manure Dung produced greatest vigour though the results from shoddy and complete artificials were similar Dried blood manure with and without potash gave relatively poor vigour and the yields from these plots were low Evidently dried blood is a poor source of nitrogen for strawberries The largest yields occurred on the dung plots Manuring did not affect the ripening season the proportions of marketable fruit in the crop or the incidence of pests and diseases

Seasonal Transmission of Cassava Mosaic

A SHORT paper by Dr H H Storey and R F W Nichols (*East African Agri J* 3 No 6 446–449 May 1938) describes a field experiment upon the transmission of cassava mosaic a virus disease Infection experiments were repeated at continuous monthly intervals for two years and it is thereby established that virus transmission is greatest from February to May and least from August to October in East Africa This would doubtless have some relation with the insect population of the area, but the practical result emerges that planting of cassava in June is most beneficial since the main period of growth is made when virus transmission is at a minimum

Separation of Mixtures of Gases and Isotopes

A NEW method for the separation of mixtures of gases which can be applied to the separation of mixtures of gaseous isotopes is described by K Clusius and G Dickel (*Naturwiss* 26 546 1938) A vertical hot surface (an electrically heated wire was used) is placed opposite a cold surface The gas mixture is between the two The various processes of thermal diffusion and convection result in a concentration of the heavier component of the mixture at the bottom of the apparatus and of the lighter one at the top Using an apparatus 65 cm long and a temperature difference between the surfaces of 300° a mixture containing 25 per cent bromine and 75 per cent helium was completely separated With an apparatus 1 metre long and a temperature difference of 600° pure carbon dioxide was obtained from a mixture of 40 per cent carbon dioxide and 60 per cent hydrogen With normal neon in an apparatus 2 6 metres long and a temperature difference of 600°, the proportion of isotopes in the gas drawn off at the bottom of the apparatus was ^{20}Ne 68 4 per cent, ^{21}Ne 0 6 per cent, ^{22}Ne 31 0 per cent whereas normal neon contains ^{20}Ne 90 0 per cent ^{21}Ne 0 3 per cent ^{22}Ne 9 7 per cent When normal hydrogen chloride containing 23 per cent $H^{37}Cl$ and 77 per cent $H^{35}Cl$ was used, the concentration of $H^{37}Cl$ in the gas obtained at the base of the apparatus was increased to 40 per cent The atomic weight of the chlorine in this mixture is 35 56, 0 10 units greater than the international value of 35 457

Protection of Telephone Circuits

To the *Strowger Journal* of July published by the Automatic Telephone and Electric Co Ltd of Liverpool, Mr T B D Terroni communicates an instructive paper on the protection of telephone circuits from inductive interference He first refers to the excessive voltages which occur on telephone lines due to faults on power transmission lines These induced voltages are sometimes of sufficient magnitude to be a danger to telephone employees and to cause great damage to telephone apparatus This type of problem occurs on railway systems where privately owned telephone lines run parallel to the track close to the main high tension distribution network The telephone lines are used for telephony, signalling and the remote control of sub stations from a main control station The danger can be obviated by means of a large inductive coil, called a drainage coil, connected between the two wires of a telephone line with its mid point in contact with the earth A further source of disturbance arises from the fluctuations of the earth potentials near a power station, when an earth fault occurs The fault acts as a source of power and the station earth acts as a sink so that currents flow through the earth The potential of the earth in the vicinity of the power station may be so high as 3,000 volts above the earth potential at some distance away When British P O lines are hired to operate between 132 kv grid sub stations and a central indicating station trouble is obviated by terminating all the P O circuits in special isolating transformers Cable circuits are much more immune from lightning induction trouble than overhead lines In desert areas open wire lines are known to experience high voltages as the result of sand storms The voltages appearing in the telephone loop are probably due to the charging up of the two conductors by the highly charged particles of sand The use of neon arresters to discharge these potentials to earth give rise to acoustic shock in the telephone receiver This is due to the repeated discharges of the lines to earth through the neon tubes, which do not necessarily flash simultaneously This is remedied by using the new atmite protectors

Atomic Weight of Carbon

E Moles and A Escribano have recently re determined the atomic weight of carbon (*Comptes rendus*, **207**, 66, 1938) The method involved the determination of the limiting densities of carbon dioxide and oxygen, this being carried out by adsorbing known volumes of the gases on charcoal at the temperature of liquid air, the charcoal being weighed before and after the adsorption The determinations were made at 760 mm and 380 mm pressure, and the limiting density was obtained by extrapolating to zero pressure assuming the variation to be linear The values obtained for the limiting densities were oxygen 1 427644 gm per litre, carbon dioxide, 1 963340 gm per litre This gives 44 0074 for the molecular weight of carbon dioxide, and 12 0074 for the atomic weight of carbon This is almost identical with the value obtained by Moles and Salazar in 1934 from the ratio CO O_2, but differs slightly from the value (12 010) accepted by the Committee on Atomic Weights of the International Union of Chemistry the eighth report of which is just published (*J Chem Soc*, 1101, 1938)

New Transformation Product in the Trans-Uranium Series

PREVIOUS work has shown that the irradiation of uranium with neutrons gives rise to three transformation series the first two of which have been followed as far as eka platinum (atomic number 96) and eka osmium (atomic number 94) respectively whilst the nature of their emitted radiation makes it possible to assume that eka gold (atomic number 97) and eka iridium (atomic number 95) respectively are further produced In the third series a β radiating uranium of half life 23 min only has been detected, which possibly gives rise to eka rhenium The three series may be summarized as follows (1) ^{92}U $+ n \rightarrow (^{92}\text{U} + n)$ $\xrightarrow[10\text{ sec}]{\beta}$ ^{93}eka Re $\xrightarrow[2\ 2\text{ min}]{\beta}$ ^{94}eka Os $\xrightarrow[59\text{ min}]{\beta}$ ^{95}eka Ir $\xrightarrow[66\text{ hr}]{\beta}$ ^{96}eka Pt $\xrightarrow[2\ 5\text{ hr}]{\beta}$ ^{97}eka Au ?, (2) ^{92}U $+ n \rightarrow (^{92}\text{U} + n)$ $\xrightarrow[40\text{ sec}]{\beta}$ ^{93}eka Re $\xrightarrow[16\text{ min}]{\beta}$ ^{94}eka Os $\xrightarrow[5\ 6\text{ hr}]{\beta}$ ^{95}eka Ir ? (3) ^{92}U $+ n \rightarrow (^{92}\text{U} + n)$ $\xrightarrow[23\text{ min}]{\beta}$ ^{93}eka Re ? The transformation products in the first two series are isomeric nuclei, those in the second series being always of longer half life than in the first This led Hahn Meitner and Strassmann (*Naturwiss*, **26** 475 1938) to look for an activity of eka iridium in the second series of long half life, since the eka iridium of the first series has a half life of 66 hr By irradiating 10–20 gm of uranium for some months with neutrons within paraffin, and examining the products, the existence of a new transformation product with a half life of about 60 days was indicated The genetic position of this product is still uncertain, but it would appear to be the eka iridium of the second series that was sought

Evolution of Eclipsing Binaries

DR ZDENĚK KOPAL has recently published a paper (*Mon Not Roy Astro Soc* **98** 8, June 1938) in which he examines the fission theory of the origin of binaries and also the question of an evolutionary progression or of a statical interpretation as suggested by their physical properties It is well known that the ratio r_1/r_2 where r_1 and r_2 denote the radii of the primary and secondary, respectively, decreases with an increase in the separation of the components Thus in the closest systems the primary is much larger than the secondary, the reverse being true in the widest systems, and the present separation is a rough criterion of the stage of evolution, provided the components were originally in contact A difficulty arises here The total angular momentum of the system resides chiefly in the orbital momentum and as separation can be effected only by internal action, such as tidal friction, there is little scope for such taking place at the expense of the rotational momenta of the constituent stars It appears that the eclipsing systems must have larger stores of angular momenta in the rotation of their components than can be obtained on the assumption that they rotate as rigid bodies with constant Keplerian angular velocities It is suggested that the interior may rotate more rapidly than the surface layers If this took place, so that rotational and orbital momenta are comparable, observational facts are not essentially incompatible with the fission theory

Sixteenth International Physiological Congress

FOUR successive international congresses, on cytology, physiology, veterinary science and history, respectively, have been held in Zurich this year. Each physiologist who had given his address, found in his room a packet containing a badge with his name on it, a list of members with local and home addresses, a small book dealing with the life and work of Albrecht von Haller, a copy of a special number of the *Schweizer Medizinischer Wochenschrift*, a book of abstracts of communications (if this had not been sent in advance), a history of the congresses, and travel folders about Switzerland and Zurich.

The Congress met without any formalities in the hall of the University on the evening of August 14. The president, Prof. W. R. Hess, opened the congress next morning in the 'Auditorium Maximum' of the Technische Hochschule. After welcoming the members of the Congress, he thanked Dr. K. J. Franklin and the Physiological Society of Great Britain and Ireland for making it possible to distribute the "Short History of the International Congresses of Physiologists" to all those present, and said that he thought that this would be of great value in fixing the tradition of these congresses (cf. NATURE, July 30, p. 222). This year marked the truly physiological hemicentenary of the first Congress, which was conceived in 1888 and met a year later, and the president expressed the gratitude of those present to the founders. Five survivors of the first congress were present, and telegrams of greetings and gratitude were approved by the meeting and dispatched forthwith to others who could not come. The meeting stood in silence to express its sorrow for the loss of those physiologists who had died in recent years, with particular mention of Pavlov, Johansson, Fredericq, Haldane, Cremer, Macleod and Abel. The president hoped that the present Congress would be worthy of the high ideals of its early predecessors.

The rector of the University of Zurich, Prof. E. Howald, welcomed the Congress in German on behalf of all the seven Swiss universities, and added that he was happy to be able to say that, in this particular matter, the universities were unanimous. The Congress was also welcomed in two other official Swiss languages—French and Italian.

Prof. L. Lapicque spoke in honour of the jubilee as a member of the first Congress. He was glad to see so many young people carrying on the work of physiology, and happy to think that once this work had been published and distributed to the libraries of the world it would live, although more concrete things might be destroyed. Since the last congress, the political situation had become less stable, and the Congress was fortunate in meeting in a country that was famous for its international atmosphere.

Sir Henry Dale spoke on behalf of all in English, which experience had taught him to be one of the unofficial languages of Switzerland. He thanked the president, and those others who had spoken in welcome. He thanked Prof. E. Rothlin, and those others who had organized the Congress. They had done much to re-establish the early traditions of friendly informality described by Dr. Franklin. Physiological congresses should not be associated with formal official receptions, and members should represent nothing but devotion to physiology and friendship for other physiologists. Switzerland had been proposed as a place for the first Congress because it was central, hospitable and attractive. The sixteenth Congress was glad to be able to meet in Switzerland not only for these reasons, but also because of the great scientific achievements of Swiss physiologists.

The scientific meetings started on Monday afternoon, and continued each morning and afternoon until Friday, with a break on Wednesday afternoon, which was devoted to an expedition on the Zurichsee to Rapperswil. Meetings were held simultaneously in five large lecture rooms in the Technische Hochschule, which is extraordinarily well adapted for the holding of congresses. The afternoons were mostly devoted to arranged discussions on chosen subjects—an innovation which was generally considered a great success. Each discussion was opened by two chosen speakers, and an abstract of their contributions was circulated some weeks in advance. They were followed by other speakers, most of whose contributions were also abstracted in a second volume circulated just before the Congress. At intervals the discussion became general, and arrangements were made by which it was possible for the chairman to invite particularly obstinate disputants to withdraw to another room so that the meeting might continue. There were also in the original programme about 330 individual communications, summaries of most of which were contained in the second volume of abstracts. These were grouped according to subject, and the discussions which arose were sometimes as interesting as the arranged discussions, and were continued in neighbouring cafés or in the *Studentenheim*, where meals were provided for the members of the Congress.

There were about fifty demonstrations, half of which were permanently on view, and the other half were each shown twice. The programme also contained twenty-seven films, some of them coloured, which were each to be shown twice between 5 and 6.15 p.m. on different days.

It is difficult to give an account of the scientific results announced at such a congress. The book of abstracts gives an interesting cross-section of the physiological thought of the day, but it takes some time to read it all, and there are probably few who could criticize it all. Papers which sound very good in abstract often sound less good when they have been criticized in the meetings. No one person could attend more than about a fifth of the meetings, and it is difficult even to be certain which papers have actually been delivered. The following papers, however, deserve special mention for various reasons.

Prof. W. R. Hess demonstrated ingenious and interesting methods for stimulating or destroying subcortical areas of the brain and observing the results. H. Theorell advanced a formula for the prosthetic group in cytochrome *c*. V. Menkin described the isolation from inflammatory exudates of a crystalline polypeptide 'leukotaxine', which increases permeability and attracts leucocytes. W. Feldberg and C. H. Kellaway presented evidence that the response of cells to injury is partly due to the liberation of lysocithin R J Williams described the isolation and properties of pantothenic acid—a universal growth stimulant present in all cells J F Toennies presented evidence that sensory stimulation may evoke a reflex which leads to the appearance of antidromic impulses in dorsal spinal roots A v Muralt demonstrated an apparatus which plunges nerve trunks into liquid air while impulses are actually passing, so that various evanescent effects of the impulses can be detected F Schutz demonstrated an apparatus for studying adsorption on foam, which may be useful in separating substances of physiological importance J S Fruton described the results of the study of the action of various proteinases on simple peptides, which show that they may act specifically on the link between one particular pair of amino acids A C Ivy demonstrated the masculinization of female rat embryos by the injection of male hormone into the mother during pregnancy and also the reverse effect on male embryos Another demonstration showed the same effect as the result of the injection of the embryos themselves by laparotomy E H Venning and J S L Browne described the results of a study of the physiology of progesterone by estimating its excretion product in the urine R D Wright and H W Florey described interesting experiments on the secretion of the colon L A Maynard, C M McCay and G Sperling demonstrated experiments in which rats lived longer than normal rats and retained their youthful appearance, when they were fed on a diet which was deficient in calories, but otherwise complete

The most popular discussions were on urinary excretion, the chemical transmission of nervous impulses steroids, the adrenal cortex and the hypophysis It was unfortunate that the last two of these discussions were held simultaneously

The pharmacologists held a special meeting at which they discussed the scope and future of their science Sir Henry Dale accused them of not taking an active interest in the important new remedies which are being introduced so rapidly, and of leaving the practical application of hormones, vitamins and chemotherapeutic agents to physiologists, biochemists and pathologists, who often have no medical training Various speakers replied that pharmacological teaching does in fact keep up to date, and that pharmacological research is more likely to be fruitful if pharmacologists are allowed to study what interests them, than if they are diverted to the study of the practical applications of the work of others Pharmacology has been handicapped because it has been regarded as a handmaid of medicine Its proper scope includes not only the study of the scientific basis of therapeutics, but also more general problems of how drugs act methods of assay and standardization, the absorption and fate of drugs, factors determining the intensity of their action and their toxic effects not only on man but also on other forms of life such as insects weeds worms protozoa, and bacteria The pharmacologist must know something of many sciences, but diversity of interests has been stimulating in the past and is likely to be so in the future

On Thursday evening the members of the Congress were divided into groups with common interests, and entertained to dinner in various parts of Zurich Interesting speeches of welcome and of gratitude were made and there were various other postprandial entertainments

The final meeting was held on Friday afternoon Prof A V Hill presented the report of the permanent International Committee Prof L A Orbeli was elected to succeed Pavlov on this committee and there was some general discussion of procedure Sir Henry Dale on behalf of the Physiological Society, invited the Congress to meet in England in 1941 and this invitation was accepted Prof Houssay put forward an invitation to Buenos Aires in 1944 which was received with enthusiasm

The Swiss committee is to be warmly congratulated on the arrangements for this Congress, which were simple and worked smoothly and without delay Membership was limited to genuine physiologists approved as such by national committees, so that the temporary physiologists who have attended some recent congresses were excluded, but this arrangement is unfortunately open to abuse since it makes it possible for genuine physiologists to be excluded for political reasons About 1 100 members registered, and they were officially accompanied by 260 other persons There were no Russians, but most other nations were well represented A number of Spaniards, including Prof Negrin, were able to come

J H Gaddum

Twelfth International Horticultural Congress

THE formal opening of the Twelfth International Horticultural Congress took place at 11 a m on August 12 in the Plenary Hall of the Congress Building (Kroll Opera House), Berlin, when the president, Herr R Walther Darré, Reich Minister for Food and Agriculture and Reich Peasant Leader gave a speech of warm welcome to all members, who represented about fifty nations Addresses were also delivered by Herr Johannes Boettner, managing president, Prof F Angelini, first vice president of the Congress, and Dr J J L van Rijn, vice president of the International Institute for Agriculture, Rome The British delegation was headed by Dr H V Taylor, of the Ministry of Agriculture, and included Sir Arthur Hill, Sir Frank Stockdale, Colonel F R Durham, R G Hatton (East Malling), F J Chittenden and Dr M A H Tincker (Wisley)

In view of the numerous and varied horticultural problems to be discussed during the week, twenty sections were set up embracing all branches of horticulture, such as growing of fruits and vegetables, nurseries, nomenclature, park and garden planning, education, physiology, etc As it was quite impossible to attend all the sectional meetings, the present account cannot claim to be complete, and mention can be made only of the few sections visited In the Section of Education great interest was shown in the international exchange of young gardeners. M Tubart outlined the existing position and made proposals for the further extension of the system In the general discussion that followed, Sir Arthur Hill gave an account of the system of exchanges in operation at Kew The first exchange was with Italy fifteen years ago and exchanges have since been made with Germany, France Belgium, Holland Denmark Norway Sweden United States Canada South Africa Australia and New Zealand

In the Section of Nomenclature under the chairmanship of Dozent A Thorsrud of Norway it was obvious that there was a real desire to arrive at practical rules for the horticulturists and there seemed to be very general agreement Unlike the proceedings at the International Botanical Congresses however the voting on the nomenclature proposals is restricted to the members of the Permanent Committee in closed session There was a very general feeling that some standard list of names of horticultural plants should be published and Miss M I Green (Kew) gave an account of the work of the Special Committee on the Correct Names of Economic Plants (including Horticultural Plants), appointed at the International Botanical Congress Amsterdam 1935 This Committee will publish a list of the correct names of economic plants in accordance with the International Rules which list will remain in force for ten years even if any of those names are in the meantime found to be not in accordance with the Rules This will be an important factor in stabilising plant nomenclature

On Monday August 15 Colonel F R Durham secretary of the Royal Horticultural Society gave a special report on the object and purpose of exhibitions and trials of new varieties in regard to the advancement of horticultural breeding and showed what a stimulating effect exhibitions and trials upon plant breeding have on modern horticulture

In addition to the more serious work of the Congress, a very varied programme of excursions and entertainments was arranged and, as the large attendances showed was much appreciated by the members Visits were paid to various biological institutions such as the Reich Biological Institute for Agriculture and Forestry the Experiment and Research Institute for Horticulture and the Botanic Garden Dahlem Botanists attending the Congress were very glad to have the pleasure of renewing their associations with the Dahlem Herbarium and Gardens where they were given a hearty welcome by the director Prof L Diels and his staff Many motor coach trips were arranged and visits were paid to well known nurseries such as that of Herr L Späth at Retzin and of Herr K Forster at Bornim

An item of feature of special interest was the exhibition entitled 500 years of German Gardening organized by the Reich Ministry of Food and Agriculture This was held in the Prussian State Library and illustrated the history of German garden flowers fruits and vegetables and the development of the style of German gardens from 1400 to 1900 Interesting illustrations from ancient books manuscripts and prints were on view also drawings engravings and oil paintings The whole exhibit was extremely well planned and repaid careful study

No account of the Congress would be complete without a word of admiration for the decorations at the Congress Buildings—there was a wealth of beautiful flowers to be seen everywhere The names of the various halls were indications of the decorations within such as the Tropical Hall the Rose Hall the Larkspur Hall and the Fruit Hall The thanks and congratulations of all members are due to the organizers of this very successful congress

---

Institution of Gas Engineers

THE seventy fifth annual meeting of the Institution of Gas Engineers was held in London on May 31–June 3 when Sir David Milne Watson received the Birmingham Medal in recognition of his encouragement of research bearing on the manufacture and utilization of gas* In his presidential address Mr H C Smith of Tottenham stated that the gas industry is under statutory obligation subject to penalties to supply gas of declared calorific value prescribed purity and minimum pressure, whereas those who sell its raw material—coal—are encouraged by statute to raise the price of coal without any obligation as to its quality He said that more than one million tons of useless material which might have been removed from the coal at the collieries had in 1937 been delivered to the gas works to the detriment of both the carbonizer and the user of coke He suggested that legislation concerning the coal industry should not stop at machinery for raising prices, but should impose obligations to supply coal of prescribed and regular quality

Mr E V Evans discussing the processing of coal said that the gas industry might be at the start of a new and greater era The industry carbonizes coal primarily for the production of gas, and the by products—especially coke—are subsidized at the expense of the gas For this reason together with legal restrictions the gas must be sold at prices which make it a luxury fuel Before it can take its place as a staple fuel gas must be freed from this burden, as is the case where it is a by product of the manufacture of metallurgical coke The ideal it has long been recognized would be to convert coal into a gaseous fuel of high calorific value Experience where natural gas and cheap coke oven gas are available shows that the advantages of such a fuel lead to an enormous expansion in its use During the last three years the Joint Research Committee of the Institution of Gas Engineers and the University of Leeds has been examining the gasification of coal under pressure It has been established that coal can be hydrogenated to yield gas and some liquid fuel without combustible residue under quite moderate pressures such as are current in steam boiler practice The results leave no doubt that the complete gasification of the ash free coal to form a high grade gas is technically feasible and it remains to establish its economic future

A paper by Dr F J Eaton on the uses of coke revealed the rapid expansion in the consumption of gas coke since scientific study had shown what merits were to be found in this somewhat neglected smokeless fuel and how they could be turned to advantage

Royal Photographic Society's Annual Exhibition

THE eighty third annual exhibition of the Royal Photographic Society at 35 Russell Square, London, will remain open until October 8

Several photographs are shown of the tracks formed by elementary particles ejected by disrupting atoms embedded in the emulsion The spacing of the grains in a track is characteristic of the particle and its energy Among the examples shown are the tracks of α particles ejected by cosmic rays and neutrons the α particles from thorium C and tracks due to protons and deuterons Another interesting photograph shows the identification of the radioactive isotope of samarium from the direct deposits of the isotopes by a mass spectrograph on the photographic emulsion Short tracks are to be seen under the isotope of mass 148

The recent theory of latent image formation by Gurney and Mott is illustrated by a series of diagrams representing the electronic and ionic processes involved Of particular interest is the photograph showing the destruction by red light of the unformed latent image at low temperatures, thus demonstrating the existence of trapped electrons

A series of ripple tank photographs illustrates the diffraction and interference effects of waves and some direct photographs of optical interference fringes are designed to show the variation of fringe width with colour Two photographs demonstrate a method of estimating the amount of odoriferous vapour given off by a flower by comparing its action with that of camphor vapour on the appearance of a talc covered pool of mercury as a monomolecular layer of the vapour forms on its surface

One of the most interesting exhibits is a 15 ft solar spectrum taken on Kodachrome film at the Mount Wilson Observatory Other astronomical exhibits include photographs of the sun s corona and prominences taken during the total eclipse of June 8, 1937 A number of very fine cloud photographs show the formation of thunderclouds and the appearance of a line squall

The use of photography in aerial survey is illustrated by photographs taken with a nine lens air camera which covers up to 300 square miles at one exposure Another aerial photograph shows the presence of archæological remains by faint markings in the soil which may be quite indistinguishable to an observer on the ground Some high speed photographs are on view one of a revolver firing taken at an exposure of two millionths of a second

A series of twenty two wedge spectrograms exhibited by Ilford Limited show that it is possible to sensitize emulsions in any selected region over a considerable range of the spectrum Kodak Limited have an interesting exhibit showing the image of a spectrum on Kodachrome film at each stage of the processing Another exhibit shows the technical basis of the Kodak wash off relief colour printing process

The exhibition also includes a number of photomicrographs of biological botanical and metallurgical subjects and others demonstrating the value of photomicrography in the detection of forgeries and other criminal investigations The radiographs cover a wide range of subject types but there is an unfortunate lack of technical data New photographic apparatus is on view in various parts of the exhibition

Decapod Larvæ of the Great Barrier Reef*

DR GURNEY describes some very interesting larvæ in his latest work The life histories of the Palæmonidæ are little known except for certain members of the Palæmoninæ, and a large series of larvæ from the Great Barrier Reef together with material from Ghardaqa on the Red Sea and from the Discovery Expedition has enabled the author to make a decided increase in our knowledge of the group, which is a difficult one

Among the Palæmonids are specimens belonging to Ortmann s larval genus *Retrocaris*, of very large size and the study of these leads to the conclusion that the larvæ of the *Retrocaris* group belong to the genus *Palaemon* or the closely related *Brachycarpus*, which, although the adults inhabit fresh water, may in certain species migrate to the sea to liberate their larvæ A summary is given of the characters of the last larvæ of *Leander* (excluding *L tenuicornis*, which differs conspicuously and should possibly be placed in a separate genus) and of *Retrocaris* (*Palaemon* or *Brachycarpus*) The larval Pontoniinæ in the collections belong to two groups, one of which, the Periclimenes group, is easily defined and a fair amount is known about them It is exceedingly interesting however, that the larvæ of *Periclimenes diversipes* and *Harpilius gerlachei* indicate quite a different generic grouping of the adults from that which is adopted by Kemp A study of the adults apparently bears this out *P diversipes* differing from *Periclimenes grandis* *P agag* and *P americanus* in almost every appendage and resembling *Harpilius* or *Coralliocaris* Larvæ of the Mesocaris group of the Pontoniinæ are much more difficult to classify The new name *Cryptoleander* has been coined for a third group including three peculiar larvæ *Anchistoides* also has very distinct features, and the late larvæ almost certainly belonging to this genus are most striking It is suggested that it should not be placed in the Pontoniinæ but in a distinct sub family

The Alpheidæ show as a rule great uniformity of structure in the larvæ, several of which are described Their main interest lies in the apparently close relationship with the Palæmonidæ Hitherto there has been a tendency to regard this family as more nearly related to the Hippolytidæ, but the discussion at the end of this paper shows that the Alpheid and Palæmonid larvæ agree in many characters, well shown in the present material The fact that a species of *Coralliocaris* was found which snapped its claws like an Alpheid is significant

---

Science News a Century Ago

London and Birmingham Railway

THE most important event in railway history in 1838 was the opening on September 17, 1838, of the whole length of line, 112½ miles long, from London to Birmingham. Parts of the line had been in use for some time, but at 7 a m on that day a train left Euston carrying the directors, the principal engineers and a few friends, Robert Stephenson, the engineer-in-chief, being in charge of the locomotive. The new portion opened on September 17 was that between Denbigh Hall and Rugby, on which is situated the Kilsby Tunnel, 2,400 yards long, which had proved most difficult to construct. Describing the opening, a correspondent of *The Times* said, "Taking this line of road as a whole, it is one of the most stupendous undertakings of modern times, and will ultimately lead to results of which it is difficult to foretell the extent"

J. D. Forbes and His Students

FORBES, when professor of natural philosophy at Edinburgh, had among his students during the session 1836–37, "Batten, Cleghorn, J Anderson, J Rankine, Harrison—the pleasantest I ever had, much occupied with experiments on radiant heat" He kept in touch with some of these and writing on September 17, 1838, to J T Harrison, who became a civil engineer under Brunel, he said . "There has been a considerable break up, of course, among your associates in the Nat Phil Class. Still, however, I have kept my eye pretty well upon those with whom you were more particularly associated and the Physico-Mathematical Society prospered last winter remarkably well . . .

"I shall be glad to hear, though I scarcely expect it, that you have not in the midst of your professional pursuits entirely lost sight of the general scientific principles which form its surest foundation I do not doubt your good-will or the clearness of your views of what befits a liberal and enlightened prosecution of your profession That I am sure you will never do ; but I rather fear that the very success to which your talents and application so well entitle you, may have already forced you to travel upon the narrow railroad of everyday applications. . . ."

The Duke of Sussex and the Royal Society

IN 1830 Prince Frederick Augustus, Duke of Sussex (1773–1843), had accepted the presidency of the Royal Society. He took office just after Babbage had published his "Reflections on the Decline of Science in England" and Sir James South had written his "Charges against the President and Council of the Royal Society" The Duke was elected by 119 votes as against 111 cast for Sir John Herschel. He held office for eight years, and when he decided to resign he wrote a letter to the Council which was published in the *Athenæum* for September 22, 1838 In the course of this letter he said : "I hope and most fervently pray that the Royal Society may long continue to prosper and flourish, but for this purpose, Gentlemen, you must avoid all matters which are of a tendency to create angry feelings, or heart burnings, on questions of a religious or a political nature. They have nothing to do with science but to create difficulties and impede philosophical researches. From these let me conjure you most cautiously to abstain."

Progress in the Gas Industry

THE majority of our large industries can claim to-day to be well managed. Two major depressions since the Great War and the need of continuous adjustment to changing world conditions, including the altered views towards labour at home, have provided a stimulus to which even the most conventional and conservative have been forced to react. The more successful industries are those which have favoured research both into new processes and to bettering existing practice. In the steel industry, for example, every time a new plant is erected—and there have been several in recent years—it represents all the most modern views with the addition generally of something new, peculiar to the particular plant. If successful, this novelty is copied in the next plant, though others in the industry can only benefit when the next new plant is built. Such an industry must bear a very high rate of depreciation if it is to replace its plant at reasonable intervals, and it has to solve some very difficult financial problems. In certain industries the amount of capital locked up in a particular type of plant is large, so that a new development which involves the scrapping of this plant whilst it is still in first-class condition is looked at askance.

Whilst it is the prime duty of management to carry on a business as it exists, seeking any and every way of increasing efficiency in all departments, nothing is lost by occasionally reviewing the possibilities in quite other directions than what is normal practice. Whilst competition should be enough to keep industrial firms alert, the great public utilities might conceivably stagnate without the pressure of public opinion.

Probably the most discussed event of the year in the gas industry is a paper by Mr. E. V. Evans, who is chairman of the Research Executive Committee of the Institution of Gas Engineers, in which views are advanced regarding the processing of coal which involve a great departure from existing practice. Inasmuch as coal is both the chief raw material and main source of political and social controversy in Great Britain, whilst each one of us is concerned in the problems of cooking and heating, it is of interest to enlarge a little on this subject.

Two large industries carbonize coal—the gas industry, which makes gas the prime and coke a subsidiary product and also undertakes the supply of gas to every room in every house, and the coke oven industry, which makes coke for the metallurgical industries and sells gas as a by-product when possible.

The Area Gas Supply Committee under the chairmanship of Sir Alexander Walker advocated in 1930 that by means of a system of ring mains this oven gas should be collected from the coke ovens and distributed by the gas companies. The city of Sheffield has adopted this practice with success, though more recently both the Lords and the Commons have given an attentive ear to the opposition of vested interests to a proposed scheme elsewhere in Yorkshire promoted by the gas companies. This incident is both regrettable and short-sighted; it is imperative, to conserve our national resources of coal, that all gas produced at coke ovens or oil refiners should be distributed through the mains of gas companies. In the United States there are many thousands of miles of pipe line serving this purpose.

The purpose of a gas company is to supply gas, and its capital and expenditure is almost entirely devoted to this. The sale of the by-product brought in a casual income which has been supplemented and made more regular since the industry has turned to perfecting at considerable cost the quality of coke both in regard to size moisture and ash content and burning qualities In addition the apparatus in which coke is used has been perfected so that the public is getting to use and to rely on it more and more causing a demand for it in the colder months which roughly balances the production by the gas industry

Mr Evans has drawn up an illuminating balance sheet on *a thermal basis* of the gas industry 300 therms are purchased in the form of coal for 25*s* that is 1 00*d* per therm by a works some distance from the collieries and a further 150*d* is spent on manufacturing costs exclusive of capital charges 72 therms are used during the process so that the cost per therm of the products is 450/228 = 1 97*d* per therm

There are three products namely 75 therms of gas 135 therms of coke 18 therms of tar The coke sells at the works at 1*d* per therm (a working loss of 0 97*d*) and the tar at 1 85*d* per therm a loss of 0 12*d* on each therm If these losses are computed per therm of gas they amount to 1 78*d* making a total manufacturing cost for gas of 3 75*d* per therm into the holder ready to be distributed If gas is to hold its own in the future it should be cheaper particularly if it is to serve—as it should—as a staple fuel and not a luxury commodity The industry in such circumstances will no longer be in a position to afford the continued production of coke the public with cheap gas as a staple fuel will not need coke as a complement Further if gas exclusively is used in a household for which purpose the existing supply mains are adequate the distribution costs will be decreased

This economic survey leads to the consideration of the technical problem of the complete gasification of coal The gas must be low in carbon monoxide and contain enough hydrocarbon gases to give it the calorific value and combustion properties which now characterize it A new process has to be invented and Mr Evans described the experimental work which has led to most hopeful results these are soon to be tested on a large scale in a specially designed plant They are based on the discovery that large yields of methane are obtained by the direct hydrogenation of coal under pressure as it is undergoing decomposition whilst its temperature is being raised from 550° to 800° C The production of the necessary hydrogen at a low cost is based on an earlier discovery by the Lurgi Company that coal gasified under pressure in the presence of steam and oxygen with a high proportion of the former yields a gas rich in hydrogen

The technical details need not concern us The picture is one of coal being charged into a vessel where it will be treated with hydrogen under pressure in such a manner that it will produce rich gas together with primary tar When rather more than half the weight of coal has gone, the rest is fed to a producer operating under pressure and supplied with oxygen and steam where it is gasified to produce hydrogen Such a works would be very much smaller than the modern gasworks purification being done by washing under pressure would be simple and there would be other advantages It would however be entirely different from the gasworks of to day

The gas industry has enterprise and public spirit enough to carry through the experiment it will take time and treasure If it succeeds the day will be nearer when all our heat is on tap the streets free from carts delivering coal and coke the skies free from smoke and our houses cleaner and more convenient

Oxford Essays on Evolution

Evolution
Essays on Aspects of Evolutionary Biology presented to Prof E S Goodrich on his Seventieth Birthday Edited by G R de Beer Pp viii + 352 (Oxford Clarendon Press London Oxford University Press 1938) 15*s* net

FOR close on half a century Prof E S Goodrich has been engaged in zoological research and teaching in the University of Oxford On the recent occasion of his seventieth birthday a congratulatory volume prepared by a number of his colleagues and pupils was presented to him Instead of following the usual method of such *Festschriften* and allowing the contributors to write on any subject they might choose, the editor, Dr G R de Beer, decided to prepare a planned volume on the more important aspects of modern knowledge concerning evolution He secured the collaboration of twenty authors each of whom has dealt with the particular branch of the subject to which he has given special attention The result is a work which has value as a summary of existing knowledge and current opinion quite apart from the circumstances that led to its publication At the same time the very completeness of the survey bears witness to the vitality and catholicity of the Oxford school of zoology while the fact that so many of the authors find occasion to quote from the writings of Prof Goodrich himself is evidence of the many sided inspiration which that school has received from him

It is not possible here to comment on more than one or two of the nineteen essays contained in the volume although all of them merit the attention of every biologist The veteran Sir Edward Poulton contributes in the first essay a vigorous restatement of the Darwinian (or rather Batesian) explanation of insect mimicry a restatement that will perhaps find a more ready hearing than it might have found say twenty five years ago Dr Julian Huxley discusses the present standing of the theory of sexual selection and concludes that the hypothesis of female choice and of selection between rival males is inapplicable to the great majority of display characters

Mr E B Ford and Prof J B S Haldane both write as geneticists the former on the genetic basis of adaptation and the latter on the nature of inter specific differences One gets the impression that the chasm which until a few years ago yawned between genetics and the other branches of biology is being spanned and if the bridge is not yet fit for heavy traffic the foundations of a permanent structure are becoming visible Dr G R de Beer in an essay on embryology and evolution is largely concerned with attempting to redefine the concept of homology in terms furnished by the results of experimental embryology and trying to find what truth may remain in the famous theory of recapitulation The latter theory also comes under consideration by Prof Garstang and Dr R Gurney in discussing the descent of Crustacea from trilobites Mr J Z Young discusses the evolution of the nervous system making some points of importance that will be new to most biologists Dr W K Spencer describes some primitive fossil echinoderms and makes some very interesting suggestions as to their probable habits but perhaps over estimates the capacity of non specialist readers to follow his descriptions Dr H A Baylis s chapter on helminths and evolution provides an excellent example of the way in which the detailed knowledge of the systematist can be brought to bear on some of the fundamental problems of biology

One complaint must be addressed to the editor The deplorable modern innovation of omitting the titles of papers from the lists of references makes these lists of singularly little use W T C

School Physics

(1) A School Physics Revision Notes and Questions
Hydrostatics Heat Light and Sound By S R Humby and F W Goddard Pp viii + 235 (London New York and Toronto Longmans Green and Co Ltd 1937) 3*s*

(2) Concise School Physics
Mechanics By R G Shackel Pp vii + 184 (London New York and Toronto Longmans Green and Co Ltd 1937) 2*s* 9*d*

(3) Electricity and Magnetism
By Dr R G Mitton (Dent s Modern Science Series) Pp x + 272 (London J M Dent and Sons Ltd 1937) 3*s* 6*d*

SCHOOL text books of science sometimes fall between two stools They should either be so fully written and so easily read that the pupil can learn his subject from them with the minimum of help from his teacher or they should be so strictly abridged that the teacher is not embarrassed when he tries to develop the work along his own lines Too often a beginner is only hampered by having a new subject presented to him in two different ways at the start Messrs Humby and Goddard and Mr Shackel have avoided this difficulty in their two books in which there are many points of resemblance for they offer the pupils a clear outline of their subjects supported by a great number of questions taken from examination papers of matriculation standard

(1) The authors of A School Physics state that their book is intended primarily for use as a final revision for students taking the various school certificate and matriculation examinations and for those beginning an advanced course in physics For this purpose it should prove very useful If we must have examinations we may as well use that incentive to the full A School Physics deals with hydrostatics heat light and sound but not with electricity

(2) Mr Shackel, in his book, confines himself to mechanics, but he includes hydrostatics, elasticity, surface tension, viscosity, diffusion and osmosis under this heading The writing is very condensed and the general method of treatment is to define and elucidate a principle, then to provide experimental verification and lastly to proceed to practical application Some of the experimental work which Mr Shackel mentions is novel and many of his applications are modern The frequent historical notes, which add to the attractiveness of the book for the adult, are perhaps too concise to make much appeal to the student, unless—as the author probably intended—they receive amplification from the teacher This book, like the one mentioned above, should prove an effective tool to use in preparing pupils for matriculation and kindred examinations, but—better than that—it provides a sound introduction to more advanced work in physics For students of average ability, it may prove difficult to follow, unless they get considerable help from their teachers The latter should find it very convenient to use with their classes

(3) Though Dr Mitton is concerned with the formal development of one branch of science, his method is to proceed from the practical aspects in order to elucidate principles Thus, in his preface, the author says Most students are interested in the practical applications of electricity, and it must be the aim of a text-book to develop this latent interest, as well as to present the fundamental principles of the subject in an attractive form" "For this reason," he goes on to say, "although the requirements of students preparing for School Certificate Examinations have been a primary consideration, the scope of this book has not been limited by a narrow interpretation of the requirements of any examination syllabus, but has been extended to include a short account of alternating currents, and of modern discoveries in electricity"

A perusal of the book certainly bears out his claims The treatment is sometimes rather didatic, but there is a unity and a coherence much more marked than usual in this type of work, and the numerical examples given in the text are often admirably chosen to help the argument When it is shown, for example, that to transmit electrical energy at 220 volts instead of 132,000 volts without increasing the loss would need a cable of more than 22 feet in diameter, the object of transformers is certainly brought home ! The chapters on static electricity make somewhat heavy reading, but the whole book strikes one as a sound, well planned piece of work, which is both attractive and stimulating

---

The Study of Earthquakes

Theoretical and Applied Seismology
By Dr Akitune Imamura Pp xi + 358 (Tokyo Maruzen Co, Ltd, 1937) 7 yen

SINCE the early years of the present century, Prof Imamura has been widely known as one of the most active and capable of Japanese seismologists On the death of Prof Omori in 1923, he succeeded to offices held by him, his first duty being the investigation of the great Kwanto earthquake of that year He has also made valuable studies on the displacements of the crust in connexion with Japanese earthquakes In 1931, he retired from the professorship of seismology in the Imperial University of Tokyo, and the notes that he had collected for many courses of lectures form the foundation of the present volume

A noteworthy feature of the book is the number of references to the work of foreign seismologists Yet there are some curious omissions It is difficult to understand how, in a volume so largely devoted to the earthquakes of Japan, the achievements of Prof Milne in that country should never once be mentioned There are brief references to his catalogue of destructive earthquakes, to his well known seismograph and to the reports of the British Association Committee, but no one would gather from these pages that he was the founder of the Seismological Society of Japan, or the man whose work led up to the present organization of earthquake studies in that country Again, in the chapter on "some great earthquakes", the descriptions of the California earthquake of 1906 and the Messina earthquake of 1908 are both founded on preliminary reports of Prof Omori The detailed accounts of the former earthquake edited by Profs Lawson and Reid and of the latter written by Prof Baratta are not referred to

Serious as these omissions are, Prof Imamura's book is a valuable addition to our list of earthquake manuals Some of the sections dealing with Japanese earthquakes will be found of special interest to European readers, such as those on the displacements of the crust connected with great earthquakes, the Sanriku sea-waves of 1896, the distribution of the earthquakes with the catalogue of severe earthquakes since 1596, and the accounts of the great earthquakes of 1707, 1891, 1923 and 1927

In one important respect the book differs from its predecessors in the special attention devoted to the practical applications of seismology The final chapter on the mitigation of earthquake disasters deals with the selection of the site the construction of earthquake proof buildings and the measures to be taken if fires should break out ending with a section as useful as it is unusual on the behaviour of human beings during earthquakes The chapter on the effects of earthquakes on water closes with similar and equally practical advice on the mitigation of the disasters caused by earthquake sea waves

Aluminium, Potassium and Magnesium

Gmelins Handbuch der anorganischen Chemie Achte vollig neu bearbeitete Auflage Herausgegeben von der deutschen chemischen Gesellschaft (Berlin Verlag Chemie G m b H 1937)
(1) System Nummer 35 Aluminium Teil A Lief 5 Legierungen von Aluminium mit Zink bis Uran Pp 683 886 + xvi 24 75 gold marks
(2) System Nummer 22 Kalium Lief 3 Verbindungen bis Kalium und Tellur Pp 515 804 35 25 gold marks
(3) and (4) System Nummer 27 Magnesium Teil A Lief 1 Vorkommen Darstellung des Metalls Pp 156 18 gold marks Teil A Lief 2 Eigenschaften des Metalls Pp 157 372 25 50 gold marks
(5) Magnesium Legierungen Patentsammlung Von A Grutzner unter Mitarbeit von G Apel und C Gotze Zugleich Anhang zu Magnesium Teil A in Gmelins Handbuch der anorganischen Chemie Pp vii + 192 15 gold marks

(1) THE systematic description of the alloys of aluminium is continued in the part of Gmelins Handbuch under notice A long range of metals including zinc mercury tin lead chromium tungsten and most of the rarer metals is covered and more than a hundred diagrams illustrate the variations in physical properties

Aluminium and zinc mix completely in the liquid condition but at room temperature a maximum solubility of 18 per cent of zinc is indicated by a marked discontinuity in the conductivity curve Solubility in caustic alkalis falls rapidly and in dilute acids rises as the proportion of zinc is increased both curves showing breaks at the concentration corresponding to the composition Al_2Zn_3 Aluminium dissolves very slightly in mercury amalgamation occurs at the boiling point of the latter and also in certain chemical reactions but the products in the latter case are never uniform The amalgam reacts easily with water and provides a convenient neutral reducing agent in organic reactions

Lanthanum and cerium show pronounced maxima at temperatures somewhat above 1400° C Tin and aluminium can be melted together and form an eutectic with 99 5 per cent of tin but in the solid state the mutual solubilities are extremely small and the alloys are readily corroded by water Lead mixes only to a very slight extent even in the liquid condition whilst the data about chromium are contradictory

(2) Compounds of potassium with bromine iodine sulphur selenium and tellurium are described in the second volume under notice Naturally the halides and sulphate receive most attention For exact work on the determination of equivalent weights pure potassium bromide has been prepared from bromine vapour and neutral potassium oxalate which react with liberation of carbon dioxide

The solubility of potassium iodide in different solvents has received much attention The diagram illustrating the solubility of the salt in liquid sulphur dioxide shows the existence of two compounds containing four and fourteen molecules respectively of sulphur dioxide combined with one of potassium iodide Several anhydrous polyhalides of potassium with either three or five halogen atoms per molecule have been isolated but polyiodides are unknown in the unsolvated condition Thus the tri iodide is combined with one molecule of water or two of benzonitrile A poly iodide of the composition $KI_9, 3C_6H_6$ has also been obtained

The complex system between potassium sulphate sulphuric acid and water is described in full detail Potassium sulphate behaves in a remarkable fashion with potassium fluoride since the compound which they form is only stable above 578° C Undoubted evidence of its existence is provided not only by the appearance of two eutectic points on the phase rule diagram but also by the strongly marked depression in the curve of specific conductivity

(3) and (4) In recent years magnesium has sprung into prominence on account of the importance of some of its alloys Although exact production figures are not yet available it has been estimated that the world s output of the metal has risen from about 300 tons in 1926 to many thousands of tons per annum, the demand having

increased suddenly about three years ago. Minerals containing magnesium were used by the ancient Greeks and Romans, but it was Black who first distinguished clearly between lime and magnesia in 1755 In 1808 Sir Humphry Davy obtained an amalgam but failed to isolate the metal. Twenty years later, Bussy reduced the fused chloride to the metallic state with the vapour of potassium, but Davy's original electrolytic method was successfully modified in 1852 by Bunsen In view of the astonishing increase in the industrial applications of the metal in recent years, it is perhaps surprising that this method has not only survived but also has practically eliminated other competitive processes. The chief difficulty to be overcome is the elimination of water from the fused chloride, since even traces of moisture cause hydrolysis and the formation of an insulating layer of oxide Hydrolysis is considerably lessened when potassium chloride is present, and sometimes carnallite is used. The addition of potassium chloride causes the metal to sink to the bottom in spite of its low density

Complete dehydration of magnesium chloride is, however, difficult and other industrial processes have been successfully operated. Thus the oxide can be reduced with carbon in the electric furnace and a modification of the Hall-Héroult electrolytic process for aluminium has been adapted for magnesium Magnesium is the lightest of all metals to withstand atmospheric corrosion, and moreover in the pure state it possesses very valuable mechanical properties. Numerous references are given to technical methods of manufacture and there is a very full description of its physical and chemical properties, including recent work on its atomic structure, isotopes and nuclear transformations under bombardment.

(5) An alphabetical register of all known alloys of magnesium, arranged on the lines of those already published for steels and aluminium alloys, with remarks on their principal uses and references to the patent literature of Germany, Great Britain, France, Austria, Switzerland and the United States from 1909 to the end of 1936, should prove invaluable to those engaged on research work in this technically important and rapidly expanding industry References to journals are excluded, since they are given in abundance in the text

Phenomena of Gaseous Discharges

Elektrische Gasentladungslampen
By Dr W. Uyterhoeven Unter Mitarbeit von Ing K W Hess Pp ix + 364 (Berlin Julius Springer, 1938) 36 40 gold marks

THE scope of this book is wider than its title suggests , this applies especially to the first two parts—the seven chapters dealing with electrons and atoms, and the general theory of discharges in gases

These seven chapters include, in only 140 pages, practically all the fundamental physical ideas from the kinetic theory of gases to the complete discussion of the positive column The literature up to about 1937 is considered In order to cover as much ground as possible in this comparatively small space, the discussion of individual processes has had to be somewhat condensed However, the non-specialized engineer will find the book provides quite a satisfactory account of the various problems, while the student reader who requires detailed solutions will obtain further information from the numerous papers which are cited at the end of the book and co-ordinated with the individual chapters In a future edition this part of the book could, perhaps, be extended, especially as attempts have recently been made to revise the theory of the positive column, which is of prime importance in gas discharge phenomena

Chapters viii and ix deal with light and vision, and contain a survey of colorimetry based on modern concepts, together with a short review of photometry and the efficiency of illuminants

The later half of the book is devoted to discharge lamps—neon and mercury high-pressure (1–10 atm) and super-high pressure (80–100 atm) Some of these chapters will be of permanent value in so far as they discuss the complicated physical *problems* connected with the operation of such discharges and the many practical problems of auxiliary gear The *solutions* may be looked at from a different angle in a few years time, and in addition development of the special lamp types is very rapid The majority of the types discussed are Continental and to a great extent are taken from those of the Company in whose laboratory Uyterhoeven has done important work on the development of the discharge lamp This slight bias is perhaps not unnatural, as the author must have had more information from his own Company than from others

Uyterhoeven's book can be recommended as an interesting survey of a technical field which may prove absorbing to many engineers. Some of the problems also suggest lines for further research.

Our Daily Bread·

a Geography of Production By Sir Daniel Hall Pp xi+169 (London John Murray 1938) 6s net

WE have travelled far since Mrs Mangnall s 'Historical and Miscellaneous Questions , first published in 1800, was widely used for initiating youth into an encyclopædic knowledge that ranged from the architecture of the universe to such lowly things as the nature and sources of hemp and ginger The seeming omniscience of the author no less than the illogical sequence of much of the subject matter, makes amusing reading to day and gives us some justification for pluming ourselves on progress since achieved Sir Daniel Hall s latest book written primarily for use in urban schools marks in a very striking manner the antithesis between the old and the new ways of imparting information In simple language and easy flowing style he relates all those facts about the sources of our daily foodstuffs that a developing adolescent ought to know and a slight discursiveness here and there, as well as many excellent pictures and a few maps adds interest to his narrative

In one respect however the book resembles Mangnall it is purely informative and therefore invites a criticism which the author seems to expect when he says Education consists in something more than handing out information but none the less it is a thin and colourless life that does not start with a basis of facts To the scientific mind a factual basis is a *sine qua non* of every mental discipline never theless for the very young fairy stories have much to commend them, and later on a trained imagination is essential for perceiving relationships between facts for trying to explain differences between related facts, and for drawing conclusions by putting two and two together We may therefore hope that the author will follow up this excellent introduction to the facts of agriculture with a more ambitious book that will not only inform the developing mind but also stimulate it to *think* *Primum pensare deinde vivere*

E H T

Surface and Radiological Anatomy

for Students and General Practitioners By Prof Arthur B Appleton Prof William J Hamilton and Dr Ivan C C Tchaperoff Pp xi+311 (Cambridge W Heffer and Sons, Ltd , 1938) 15s net

THE collaboration of two professors of anatomy with a radiologist has resulted in the production of a work which marks a new departure in the study of surface anatomy, and should be highly appreciated by the medical practitioner and student The work is divided into six parts, devoted respectively to the upper limb, chest and back, abdomen, head and neck, vertebral column and lower limb, preceded by an introduction containing an account of radiological technique There are three appendixes, containing tables of ossification, a summary of ossification and segmental innervation of muscles The radiological methods include œsophagoscopy, gastroscopy, cysto scopy, ventriculography and encephalography

The Subject Index to Periodicals, 1937

Pp xxix+292 (London The Library Association, 1938) 70s

THIS is the twenty second year of publication of the Subject Index to Periodicals prepared by the Library Association The Association and its general editor Mr T Rowland Powel are to be congratulated on the issue of the volume for 1937 only five months after the close of that year

This volume introduces a new and valuable feature in a Location List' which tells the reader where he may consult the periodical mentioned More than 170 libraries in the United Kingdom are mentioned in the list In this list the reader is told in which libraries each of the 584 periodicals indexed may be found There is of course no guarantee that the library in question would be prepared to lend its periodicals to borrowers Of the periodicals indexed 535 are English and American 27 French and Belgian 20 German and 2 Italian

The articles indexed are arranged under subject headings such as hygiene mine accidents microscope, photography The subject headings are arranged in alphabetical order and are chosen from the alpha betical subject headings of the Library of Congress U S A with modifications and additions to suit British practice Verse and fiction are not included

With some important exceptions, periodicals covered by the following publications are not indexed *Agricultural Index Engineering Abstracts Engineering Index Index Medicus Journal of the Society of Dyers and Colorists, Photographic Abstracts Revue de Géologie Royal Meteorological Society Bibliography Science Abstracts A and B Textile Institute Journal* There is no doubt that the Library Association is doing valuable work in preparing this annual index to the contents of periodicals

Diet and Cancer

an Experimental Study By Dr N Waterman Pp v+96 (Amsterdam D B Centen s Uitgevers Maatschappij 1938) 2 50 dollars

AS the result of his investigations at the Leeuwen hoek Cancer Research Institute, Amsterdam, Dr N Waterman while admitting that his results are neither complete nor definitive, maintains that the influence of different foodstuffs on a definite experimental form of cancer is incontestable His experiments, which were carried out on mice develop ing tar cancer, showed that of the classical foodstuffs (proteins carbohydrates and fats) only animal fats appeared to have a definite deleterious effect the malignancy of the process being increased to a marked degree As regards vitamins, increase of vitamin A intake had an undoubted, if not very marked mitigating effect on the course of tar carcinoma administration of vitamin B_1 did not have the un favourable effect in tar cancer which it had in inoculated tumours , and vitamin C delayed the formation of carcinoma and increased the duration of life

A Text-Book of Convergence

By W. L. Ferrar. Pp vii + 192. (Oxford: Clarendon Press; London: Oxford University Press, 1938.) 10*s*. 6*d* net.

IN this book, the theory of convergence is developed on two fundamental assumptions. The first of these is concerned with upper bounds, namely, that a certain set of numbers has in it a least number; while the second refers to irrational number as the limit of a sequence of rational numbers, namely, that every irrational number is the limit of a monotonic increasing sequence of rational numbers. With the aid of these assumptions, the theory of convergence is developed without recourse to the properties of Dedekind cuts. The 'real' number appears only in the appendix, where the assumptions used in the body of the work are proved to be consequences of the definition of real number. In the appendix also, the first of the above-mentioned assumptions appears as a theorem, and a proof of the second is given. In fact, the appendix contains as much of the foundations of analysis as is necessary to justify the assumptions made in the initial chapters of the book. A short historical survey prefacing an examination of these 'foundations' shows why such a complex structure as the Dedekind cut is essential to the definition of number.

The notation used throughout the work is one familiar to all analysts; but its use in a text-book is, as the author says, somewhat of an innovation. A great improvement on the majority of text-books is that the proofs do not teem with references to previous theorems. The references are given parenthetically if at all, and the student is advised to use them as sparingly as possible in following the proofs.

Organic Reagents for Metals and for Certain Acid Radicals

By the Staff of the Research Laboratory of Hopkin and Williams, Ltd. Third edition. Pp 156. (London: Hopkin and Williams, Ltd., 1938.) 2*s*.

THE first edition of this small work appeared in January 1933, it was reprinted in July of the same year, a second edition appeared in 1934, and now a third edition has become necessary.

About forty compounds are mentioned in the book; the systematic names (alphabetical order) are followed by trivial names, constitutional formulæ, molecular weight and salient properties. Concise directions are given for use in qualitative and quantitative work. The bibliographies for each compound are full and there is a good index. The book should be used in conjunction with "Modern Methods in Quantitative Chemical Analysis" by A. D. Mitchell and A. M. Ward.

The Conquest of Cholera:

America's Greatest Scourge. By Prof. J. S. Chambers. Pp. xv + 366 + 40 plates. (New York: The Macmillan Company, 1938.) 20*s* net.

THIS book, which is based on the study of contemporary medical literature and old newspaper files, contains a detailed and vivid account of the epidemics of cholera which devastated the United States in 1832, 1833, 1849, 1866 and 1873. In addition to the description of the epidemics, chapters are also devoted to the contributions to medical literature between the epidemics of 1833 and 1849, the work of Pasteur and the substitution of the germ theory for the miasmatic origin of disease. The text is liberally interspersed with portraits, maps and other illustrations, and a bibliography of sixty references is appended.

Weather Rambles

By Dr. W. J. Humphreys. Pp. iv + 265. (London: Baillière, Tindall and Cox, 1937.) 11*s* 6*d*.

IN the form of a series of chatty chapters, the author, whose larger books are well known to all students of meteorology, contrives to give a wealth of information concerning nearly all aspects of the weather in a simple form. The subjects discussed are much too varied to permit of summarizing in a few sentences. Starting with the tornado, or prairie twister, following on with the mysteries of the forms of solid condensation of water vapour and the problem of how the earth got its atmosphere, it ends with the problem of home-made weather, or the control of air conditions in enclosed spaces. This is no systematic text-book of meteorology, but contains a wealth of interesting information, all given in a clear and delightful style.

Climate:

a Treatise on the Principles of Weather and Climate. By W. G. Kendrew. Second edition. Pp. x + 328 + 12 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1938.) 15*s*. net.

THE new edition of Kendrew's book on climate gives an outline of the physical principles which underlie the variations of weather and climate. The effects of insolation, the relation of the distribution of pressure to wind systems, the formation of precipitation and of fog, the effect of elevation above sea-level on climatic factors, and a fairly detailed description of the weather of the temperate regions, form the most important features of the book.

This book is an interesting and valuable introduction to the study of climatology, and is so clearly written that it requires no special technical knowledge of the reader.

An Introduction to Weather and Climate

By Prof. Glenn T. Trewartha. (McGraw-Hill Series in Geography.) Pp. ix + 373 + 7 plates. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 18*s*.

THE first half of Prof. Trewartha's book is devoted to the physical bases of weather and climate. While this contains a considerable amount of information, it cannot be regarded as free from errors, and so is perhaps not the perfect introduction to the second part of the book, which deals with the classification of climates in accordance with a scheme which is a slight variant of the Köppen classification. The second part of the book is clearly written, and can be recommended as an introduction to the longer treatises on the subject.

The Orient and Europe[*]

By Prof V Gordon Childe

TEN years of excavation throughout the Old World have yielded results startling enough to affect our concrete picture of human history From this vast field I want to gather together some new facts that should mould our total synthesis But my aim in so doing will be not to attempt in an hour an impossible reconstruction of human history I shall rather focus attention on some new data which will permit a concrete answer to a rather abstract question Why is a prehistorian asked to preside over a section in this Association from which historians as such would be *de facto* excluded ? In a word on what grounds can prehistory in general and British prehistory in particular claim to be a science ?

Is prehistory experimental ? Yes but only within very narrow limits and in a restricted sense Normally only one sort of experiment is open to the archæologist an experiment that can never be repeated—I mean excavation Or does prehistory work ? Can it formulate general rules that serve as guides to successful action ? Yes but only as to how to acquire fresh knowledge

The prehistorian s aim is to reduce to an ordered and intelligible system the scattered and isolated splinters of evidence collected through surveys excavations and chance discoveries But only a few regions and short periods have as yet been so thoroughly explored and investigated that the facts of themselves make an intelligible pattern We have to fill up the gaps with guesses and assumptions

The title of my address is intended to recall an assumption which has exercised a profound formative influence on archæological studies which is indeed held by many as an axiom above discussion In 1899 Montelius stated this faith in the book entitled like my address The Orient and Europe At a time when the peoples of Europe were so to speak without any civilization whatsoever the Orient and particularly the Euphrates region and the Nile valley were already in enjoyment of a flourishing culture The civilization which gradually dawned on our continent was for long only a pale reflection of Oriental culture

In 1899 such a statement was very much more an affirmation of faith than a deduction from accumulated data

Restated in simpler but still not altogether unambiguous terms the statement quoted from Montelius resolves itself into the following propositions treated as axioms (1) Civilization in the Orient is extremely ancient (2) civilization can be diffused (3) elements of civilization were in fact diffused from the Orient to Europe (4) the diffusion of historically dated Oriental types provides a basis for bringing prehistoric Europe within the framework of historical chronology (5) prehistoric European cultures are poorer than contemporary Oriental cultures that is civilization is later in Europe than in the East To day none of these propositions except No 2 need be treated as postulates rather than as conclusions from the results of investigations for the excavations published during the last five years have provided abundant data by which to test the axioms validity

Let me first summarize the results of excavations in Hither Asia that tend to establish the first axiom—the antiquity of Oriental culture The beginning of the historical or Dynastic period in Egypt and Sumer now constitutes a fairly accurately dated horizon The coincidence of Egyptian and Mesopotamian sources is now close enough to permit of this horizon being dated with general consent about 3100 ± 100 B C The latest additions to knowledge resulting from Frankfort s masterly operations at Tel Agrab Tel Asmer and Khafaje intensify our appreciation of the high level of Oriental civilization and emphasize the long duration of the Early Dynastic Age The Sin Temple at Khafaje was rebuilt five times In the same period the Temple of Abu at Tel Asmer underwent four reconstructions

The Early Dynastic period itself was far from the beginning of urban life In the Tigris Euphrates delta it is preceded by two periods termed respectively the Jemdet Nasr and Uruk phases during which monumental buildings were already being erected At Erech below the earliest Dynastic temple ruins the German excavators uncovered the wall stumps of a gigantic edifice that had been reconstructed once or twice in the Jemdet Nasr period These walls in turn rested on ruins of a no less imposing building the Red Temple—a veritable cathedral adorned with a mosaic of clay nails and with friezes of stucco beasts The Red Temple itself was twice remodelled and was after all only the successor of a still earlier but no less monumental cathedral termed in view of its unusual stone foundations the Limestone Temple Now you do not build a cathedral every fifty years, even if it be built only of mud brick. This series of three prehistoric temples with their several reconstructions must cover a period of several centuries.

---

[*] From the presidential address to Section H (Anthropology) of the British Association delivered at Cambridge on August 22

But even in the Limestone Temple we are dealing with a highly organized urban civilization presupposing centuries of experimentation and development. Some aspects of that development are explicitly revealed in the archæological record. From the floor level of the Limestone Temple the Germans sank a shaft 17 m. or just under 60 ft. deep to virgin soil. It was dug entirely through the debris of prehistoric dwellings. As one winds down the ramp into that dizzy abyss one can distinguish in the pit wall eighteen layers marked by hearths, floors, stumps of walls, and heaps of sherds and artefacts. Admitting that I am now guessing perhaps rashly, I cannot believe that the al'Ubaid culture represented in the lower levels at Erech is later than 4500 B.C.

It has never been suggested that the geologically very recent delta of Lower Mesopotamia was the cradle of food production. It is in fact evident that the al'Ubaid farmers who settled on the freshly emerged land-surface there brought with them from older regions a culture already mature. In the last five years the excavations of Mallowan and Speiser in Assyria and Syria have given us glimpses of what preceded al'Ubaid in the Fertile Crescent. It is true that history does not fully dawn there until relatively late—until the time of the Dynasty of Akkad indeed. But relations with Lower Mesopotamia were so close and so continuous that the archæological record provided by the prehistoric levels of Gawra, Nineveh, and Chagar Bazar can be proved parallel to that from the protohistoric levels of Sumer. So when we find in Gawra XIII pottery and other relics typical of the earliest or al'Ubaid phase of Sumer's prehistory, we have no reason to doubt that al'Ubaid in Assyria is virtually contemporary with al'Ubaid in Sumer. But Gawra XIII already boasted a cluster of three handsome and monumental temples, decorated with painted buttresses and niches, and grouped round a court 20 m. by 14 m. in area.

The al'Ubaid temples at Gawra are perched upon a tell, formed from the ruins of older settlements, and rising already 25 m. to 30 m. above the plain. Below the al'Ubaid foundations come settlements belonging to the Tel Halaf culture. Mallowan found the same culture beneath, and therefore older than, al'Ubaid remains at Arpachiya, 38 ft. below the historical horizon at Nineveh and in deep layers at Chagar Bazar. The Tel Halaf culture is accordingly older than the al'Ubaid—if you want a guess, I would hazard 5000 B.C. as a moderate date—but it is no less sophisticated. Monumental circular buildings, cobbled streets, delicate and beautifully painted vases, ingeniously carved stone beads and stamps already used for sealing property attest already a well-organized society, an advanced economy, highly developed craftsmanship.

The Tel Halaf culture must have flourished for several generations. Mallowan uncovered at least five building levels at Arpachiya and seven at Chagar Bazar; and yet at Gawra, Nineveh and Chagar Bazar the oldest Tel Halaf foundations rest upon the ruins of villages characterized by painted pottery of the Samarra style. Guessing frankly once more, these might take us well back into the sixth millenium B.C.

Yet the culture revealed even in these remote depths resembles the European neolithic only in the most formal sense—in the continued use of polished stone adzes and some other tools. The earliest cultures of the Fertile Crescent, like its Early Dynastic cities, are so unlike anything we know in Cis-alpine Europe before Roman times, are economically so far ahead of Koln-Lindethal or Skara Brae or even Tószeg as to seem almost incommensurable. Yet some comparison is inevitable if Montelius's fifth postulate is to be objectively criticized.

The abruptness of the contrast may to-day be softened by reference to a region that is more than spatially intermediate between Mesopotamia and Europe.

The results of the long campaign conducted at Alişar Huyuk by the Oriental Institute of Chicago, which were published this year, have given the first definite clue to the culture-sequence on the plateau. In particular, they provide the skeleton of a chronology.

Below the Hittite foundations on the acropolis at Alişar (but not on the terrace) came a deposit with Cappadocian painted ware now termed Early Bronze Age or Alişar C. Below that, five building layers, accounting for 11 m. of deposit, represent the Copper Age or Alişar B. This must end by 2000 B.C. A beginning towards 3000 B.C. might be inferred from an imported Mesopotamian cylinder of Jemdet Nasr style, stone figurines like those regarded as Anatolian intruders in the Early Dynastic layers of Gawra and Tel Asmer, and animal pendants of stone remarkably like those from the Early Dynastic temple of Sin at Khafaje. To this same Copper Age belong the ruins and burials at Ahlatlibel near Ankara. It was a period when commerce was sufficiently organized for metal to be common and seals to be useful.

But beneath the lowest Copper Age floors, von der Osten's shaft pierced 8·5 m. of debris, divisible into seven building levels, before reaching virgin soil. The earliest Anatolian culture, represented by Alişar A is already so advanced that it is accurately termed Chalcolithic However sparingly used copper silver and lead were common enough to indicate well established commercial channels of distribution and specialized producers Stamp seals were already employed But certain pot forms and fabrics are already comparable to the Central European two handled tankards like those of the Hungarian Copper Age occur in the topmost layers only (Alişar A2) for the rest lugs take the place of handles but a distinctive shape is a high pedestalled bowl at first with a remarkably Danubian profile The fabric is self coloured black to red but generally muddy and sometimes particoloured—black inside and round the rim but brownish below on the exterior The Anatolian Chalcolithic seems rooted in the fourth millennium B C but how far back remains quite uncertain

Despite conspicuous divergences the Copper Age and Chalcolithic cultures of Central Anatolia are patently related to and continuous with those of north western Anatolia long known from Schliemann s excavations at Troy Re excavation there under Blegen has substantially enhanced the impression of the antiquity of Anatolian culture If the Americans have not yet provided unimpeachable data for determining the absolute age of the earlier cities they have at least filled in and expanded the scheme propounded by Schliemann and Dorpfeld The Troy that the Achaeans might have sacked about 1200 B C did Lord Raglan allow us to believe in a Trojan War was not VI but VIIa Troy VI goes back on the strength of Helladic imports to 1500 B C Cities V IV and III turn out to be quite important settlements divisible into several architectural levels and making up together a formidable accumulation 4 m deep Troy II thus separated from the Mycenaean horizon can no longer be brought down to the Shaft Grave epoch however neat Åberg s typological comparisons may look It is firmly anchored in the third millennium whatever its precise limits may be Troy I below it was already a city girt by an imposing wall Its citizens were executing monumental sculptures that provide a new limiting date on Montelius s assumption for the statue menhirs of Atlantic Europe By this time as Miss Lamb has shown at the contemporary Lesbian township of Thermi copper and even bronze were already being worked celts might have hammered flanges battle axes were used in war while trade brought marble vases from the Ægean Islands Remains of a still earlier phase of culture may be discerned at Kum Tepe Soundings there produced pedestalled bowls like those from the earliest Chalcolithic of Alişar that seem still missing in Troy I and the contemporary Lesbian site

The experiments in Anatolia thus go far to re enforce with objective facts the antiquity and relatively high level of Oriental culture assumed in axiom 1 Moreover taken in conjunction with Heurtley s excavations in Macedonia they concretely demonstrate connexions between Asia and Europe that are the precondition for admitting axiom 3 and provide a crucial instance for testing axiom 5 that is for comparing demonstrably contemporary cultures in Europe and Asia Heurtley has convincingly demonstrated the Anatolian ancestry of the Early Macedonian Bronze Age culture it begins with fully developed horned tubular lugs growing from the bowls rims The evolution of this odd type that appears fully formed in Europe can be traced stratigraphically on the Asiatic side It emerges as a finished product first in phase B at Thermi its earlier stages are illustrated in phase A For once we have fully documented a cultural spread which is irreversible in this concrete instance axiom 3 becomes a conclusion from ascertained facts

Implanted in Europe Anatolian culture appears poorer than its Asiatic parents Even in phase A Thermi was quite a township the contemporary Troy I a fenced city Their economy was so far advanced that copper and even bronze could be used for tools as well as weapons metal was so plentiful that quite a lot was left lying about for Miss Lamb to find The Early Macedonian settlements which are not older than Troy I give the impression of rustic villages For all the metal collected among their ruins they might be neolithic Macedonia was still veiled in mists which the Oriental sun must pierce before an economic system comparable even to the Anatolian could function

But if the Early Bronze Age culture of Macedonia is unambiguously rooted in Asia the later neolithic culture which it supersedes is no less securely linked with that of Vinca and Tordos in the Middle Danube basin beyond the Balkan ranges Comparison of the Macedonian relics with those from the Morava Middle Danube Maros sites shows that we are dealing not with two cultures but with different facies of one and the same culture We may reasonably speak of a Vardar Morava culture extending from the coasts to the Maros

How such a continuum was constituted remains a question for debate elsewhere Its absolute antiquity cannot be defined with precision For our purpose the supreme importance of the Vardar Morava complex is that it establishes at least once a continuity of culture from the Ægean to the Danube basin Whatever be the chronological horizon of that continuity its existence provides a justification for admitting axiom 3—diffusion from Asia to Central Europe is likely

Soil Erosion in India*

By Dr. R. Maclagan Gorrie

CONTRASTS WITH AMERICAN DATA

EROSION losses are less where the rainfall is well distributed, and it is now commonly recognized that erosion has most serious consequences in arid tracts. A heavy monsoon has more effect upon sloping fields than it has on neighbouring grasslands, whereas in arid climates the smaller area of fields is more carefully terraced, but the neighbouring grazing grounds are more vulnerable to infrequent but heavy downpours. This may serve to explain an anomaly that occurs in run-off intensity data. American figures worked out by Ramser and frequently quoted show the following averages in cubic feet per second per square mile, and in contrast I also quote tentative data of the same sort for Indian conditions.

RUN-OFF IN CUBIC FEET PER SECOND PER SQUARE MILE*

AMERICA	Cusecs	PUNJAB	Cusecs
Hilly timber, 10–30% slope	300	Terraced rice fields	60
„ pasture	620	Foothills afforested and with soil catching small dams	120
„ cultivated	1040	Foothills scrub forest closed to grazing	700
		„ open to grazing	1100
		„ disforested and heavily grazed	1600

* Cf. *Current Science*, August 1937, author's review of Q. C. Ayres' "Soil Erosion".

The American farmer using a motor-tractor keeps his fields large, and so the run-off from broad slopes of bare plough land is greater than from his paddocks of comparatively well clothed pastures. This also applies to Canadian and Australian average conditions and to parts of South Africa. On the other hand, the Indian peasant farmers have their fields in tiny and often well-terraced units which catch and hold the rainfall, whereas their grazing grounds are so misused and so badly protected with a mutilated plant cover that the run-off from them is far heavier. In the African dependencies, according to Sir Frank Stockdale's statement at a meeting of colonial officers held in Oxford in June 1937, "agricultural activity was as frequently to blame for erosion as overstocking with live-stock", so probably their run-off figures would be equally heavy for cropped land as for grazed land. Reliable data for run-off and erosion, and also for rainfall intensities and storm behaviour, are lamentably scarce even for our most important catchments, and a great field of work awaits the next generation of colonial research workers.

RAINFALL AND RIVER BEHAVIOUR

Mr. E. G. Bilham's paper on "Weather and Water Supply" read at the Public Works Congress, 1937, directs attention to the fact that even in Great Britain very few attempts have so far been made to correlate the loss of rainfall by evaporation, surface run-off, and seepage with the behaviour of streams. More work is required upon the actual fate of all the rain that falls upon a given type of plant cover and the contribution which this cover makes to the nearest stream in terms of surface and ground-water flow, before we can discuss intelligently the reactions of the larger rivers.

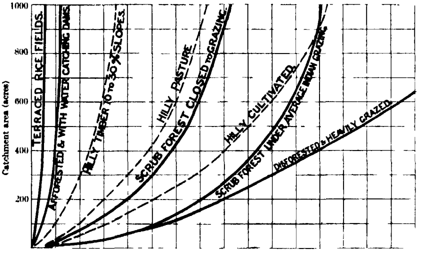
A study of the Ravi River flow records for the last twenty-five years carried out by the staff of the Punjab Irrigation Research Institute shows no significant indication of any gradual increase in number or intensity of floods nor any direct correlation of heavy floods with heavy rain. This is presumably owing to the fact that the heaviest floods arise from heavy snow-melt in the high inner hills, combining with a series of downpours falling on eroded ground in the foothills. The figures of winter flow do, however, indicate a continued deterioration in supplies available for winter irrigation. It is scarcely to be expected that a simple phenomenon such as the run-off of rain can be correlated exactly with the highly complex phenomena which go to make up the stream-flow of a large river. The Ravi River's catchment of nearly 15,000 square miles varies from 2,000 ft. to 20,000 ft. in altitude and contains several recognizable meteorological zones, so instead of looking for any correlation between rainfall and run-off for the whole, it would be better to study small individual sections and find out how each tributary reacts to the rain and snow which fall within its catchment. Unfortunately, the rainfall data in this case are for only one rain gauge for the 15,000 square miles!

NEW INDIAN STATISTICS OF EROSION LOSSES

Reliable run-off figures for forest and grassland are now available for the first time for Indian conditions. A technique of volumetric analysis of water and silt was worked out by the Punjab Irrigation Research staff at Madhopur in 1936 for a type of small isolated plot of undisturbed soil 3¼ sq. ft. in area, and this method has since been followed in forest plots at Nurpur in Kangra district. A battery of six plots gave three pairs, namely, (i) grass, (ii) grass and shrubs, and (iii) bare soil, on a slope of 1 in 4 on an eroded hillside of poor Siwalik sandstone. The grass cover over all is distinctly poor, as it is recovering slowly from previous heavy grazing The bare plots contain a little grass which has been kept clipped back with scissors They thus simulate local grazing conditions to some extent, though we have not reproduced the destructive trampling action of cattle scrambling on a greasy hill-side , and the run-off from grazed areas must therefore be considerably heavier than the figures now reported

---

* Substance of a paper read before the Royal Society of Arts on May 4.



Comparative run-off for American and Punjab conditions

American data from C E Ramser's curves (broken lines) Indian data from Pabbi Hills torrent measurements by Irrigation Branch (full lines)

The results of the first monsoon's catch is as follows :

Percentage of rain which ran off.	Grass 80% cover	Grass and shrubs 90% cover	Bare soil, grass clipped every 3 days
Out of total of 46 in on 32 wet days during July–October 1937	7	5	25
Out of total of 5½ in. in 4 hours, the heaviest single storm	2 2	1 7	6
Weight of soil lost per acre			
Carried away on 32 wet days	3,500 lb	3,900 lb	18,500 lb
Carried away by a single storm (5½ in rain)	260 lb	307 lb	3,511 lb

These figures give one food for thought when it is realized that *in a single storm the uncovered plots lost soil at the rate of 1½ tons per acre* This may be taken as a typical figure for all bare fallow fields in the foot-hills of northern India except properly levelled rice land, and they are definitely conservative for the average village grazing lands which suffer from trampling of cattle. The ordinary grazing lands also suffer from the accumulative action of shallow gullies cutting the surface on long slopes, a phase of erosion which is, of course, not reproduced in our small square plots.

Measurements reported from the Bombay Dry Farming Research Station at Sholapur (chief investigator, Mr N V. Kanitkar) show a loss of 115 tons of soil per acre per annum from a field of *jowar*, a *Sorghum* which is the most important combined grain and fodder crop in the Bombay Deccan. This loss was caused in a properly cultivated plot as a result of two very intense storms of 3·5 in and 4 3 in The total rainfall of 28 inches is usually fairly well distributed and no such intense storms occurred during the previous year when measurements were started The silt lost in these intense storms was particularly rich in valuable plant foods such as lime and potash, which were stolen by erosion, leaving the remaining soil much poorer Of the various other kinds of plant cover tested, the amount of water lost in the run-off was not strikingly different where weed or crop cover was dense The amount of soil lost where the weeds had been reserved in fallow was just one two-hundredths of the *jowar* plot, while the clean fallow of bare but uncultivated ground yielded 25 tons of soil per acre or 22 per cent of the *jowar* plot's loss These astonishingly heavy losses of silt were from very gently sloping ground, the average slope being 1¼ per cent or 1 in 80, and the data are entirely reliable, having been collected from thoroughly isolated plots I am indebted to Mr. Kanitkar and Dr W Burns for permission to use these figures

The point which this experiment has brought out is that, under Indian conditions, good cultivation on even a slight slope is no better than bad cultivation for saving soil, unless it is protected by some form of contour ridging The only sure way of reducing soil losses during exceptionally heavy storms is by contour ridging which is sufficiently deep to render each field a more or less self-contained catchment unit, so that cumulative run-off from a series of fields is prevented. The necessity for such protection is brought out by subsequent figures for these same plots in 1937, so far unpublished but furnished in a letter from Mr N. V Kanitkar, who reports that this same *jowar* plot has lost a total in the year of 133 tons per acre. This included one storm in which 2 13 in of rain in half an hour removed the huge amount of 52 tons of silt per acre.

Obituary Notices

Dr. Leo Frobenius

WE regret to record the death, at the age of sixty-five years, of Dr Leo Frobenius, the widely known German anthropologist and explorer, which took place at Biganzolo on Lake Maggiore, Italy, on June 9.

The claim of Frobenius to be remembered in the annals of anthropology will rest on his intrepidity and assiduous devotion to exploration in African lands and among African peoples In the course of his life he made no less than twelve journeys of exploration, all of a more or less arduous character, and it was on the last of those, when in 1934 he penetrated depths of the Sahara scarcely known to the Bedouin, and reached the sources of the River Ouwenat, that he contracted the malady which forced him to abandon the expedition and after some years of illness was the ultimate cause of his death

Frobenius was born on June 29, 1873, in Berlin At an early age he was attracted to the studies which became his life-work After spending some years at the ethnological museums of Bremen, Leipzig and Basle, he determined to devote himself to exploration In 1904 he founded the German Central African Research Expedition and embarked upon a journey to the Congo Basin, which lasted until 1906 In the following year he set out again, and between 1907 and 1915 completed six further journeys in Africa, visiting the Upper Niger, Timbuctoo, Togoland, the northern Sahara, the western Sudan, Khartoum and El-Obeid, Algeria and Tunisia, and finally Turkey and northern Abyssinia

Henceforth for some years Frobenius was busily engaged in working up the anthropological material he had collected in Africa, and he published a number of important books and papers dealing with his observations and conclusions He was a bold, original and independent thinker, but as he had shown in his earliest work as a young man, apt to generalize on insufficient evidence, as well as to give too wide an application to an interpretation which might be valid for a restricted area which had come under his observation. His theory of cultural continuity and cyclical development, in which he maintained that the various phases of civilization had developed in a manner exactly analogous to the growth of a living organism, was the subject of much embittered controversy

In 1924 Frobenius founded the Frankfort Research Institute of Cultural Morphology, and four years later set out with seven assistants on an expedition to Central and South Africa, in the course of which he visited and conducted investigations among the Zimbabwe ruins of Rhodesia, shortly before the excavations by Miss G. Caton-Thompson, conducted under the ægis of the British Association, which was to visit South Africa in the following year Frobenius found himself unable to accept the conclusion that these ruins were Bantu in origin, as suggested by Randall-MacIver in 1905, and as was confirmed by Miss Caton-Thompson's investigations, but arrived at the view that some six thousand years ago this area had been an outpost of Sumerian and Babylonian culture He also concluded that the iron age had begun in Africa a thousand years earlier than in Europe, iron working having entered Africa from India by way of Madagascar In the search of further evidence to support this conclusion, he afterwards visited India Two later expeditions were to Tripoli in 1932, when he studied the prehistoric course of the Nile, and in 1934 to the Sahara, as already mentioned, his last journey In this year he was appointed director of the Racial Museum at Frankfort, and for the rest of his life divided his time between Frankfort and his residence on Lake Maggiore

---

Mr. W. R. Barclay, O.B.E.

WE regret to announce that Mr William R Barclay died at his home in Birmingham on September 16, aged sixty-three years He was a leading metallurgist and one of the outstanding authorities on non-ferrous metallurgy

Mr Barclay was educated privately and later attended the Sheffield Technical College (now the University of Sheffield) During 1910–19, he was lecturer in electro-metallurgy in the University of Sheffield During the Great War, he became chief metallurgist and assistant director in the Non-Ferrous Rolled Metal Section and technical director of the Electro-Metallurgical Committee of the Ministry of Munitions. He was made O B E for his services

In 1928, Mr. Barclay became managing director of Henry Wiggin and Co., Ltd , and in 1931 he was appointed consulting metallurgist to the Mond Nickel Co , Ltd. He was largely instrumental in initiating the company research and development organization, as a result of which, in conjunction later with the International Nickel Co , innumerable new uses were discovered for nickel and nickel alloys

In 1936, Mr. Barclay was elected president of the Institute of Metals, and he was re-elected to serve a further term in 1937. It was during his presidency that the Institute decided to award an annual medal for outstanding services to non-ferrous metallurgy.

Mr. Barclay was well-known in metallurgical circles in the United States, and he was invited to deliver the Calvin W. Rice Lecture to the American Society of Mechanical Engineers in June of this year. At the same time, he was to be awarded the degree of doctor of science by the Stevens Institute of Technology. Unfortunately, owing to his illness, he was unable to attend these functions.

News and Views

Albrecht Penck

ON September 25 Albrecht Penck world famed as geologist and geographer will celebrate his eightieth birthday Born at Renditz near Leipzig in 1858 Penck was educated at Leipzig and Munich taking his Ph D in 1878 In 1885 two years after he had published his Die Vorgletscherung der Deutschen Alpen he was appointed to the chair of geography in the University of Vienna where he remained for twenty years until in 1906 he was appointed to take charge of the Museum of Marine Studies in the University of Berlin Under his direction the Museum was much enlarged and he himself made important contributions to the study of hydrography In 1922 he was made director of the Institute of Geography of the University becoming emeritus in 1927 While still at Vienna Penck had established an international reputation for his illuminating treatment of geology and geography as linked studies His Morphology of the Earth s Surface (1894) was speedily accorded recognition as a standard work Notwithstanding his numerous contributions to geography, which his widely extended travels kept in close touch with practical realities Penck s strongest claim to the remembrance of posterity will rest on his epoch making studies of the Ice Age Since the publication of Die Alpen im Eiszeitalter (1909) written in conjunction with his old pupil and friend, Ed Bruckner his classification of the four phases of maximum glaciation has been fundamental in all studies of quaternary geology and the history and chronology of early man In tendering our congratulations on this occasion to Prof Penck we hope that he may live to enjoy the homage due to his labours for some time to come

Mr H C Sampson, C I E

MR H C SAMPSON is retiring from the post of economic botanist at the Royal Botanic Gardens, Kew on September 30 Before going to Kew in 1927, Mr Sampson had gained a wide experience of tropical agriculture in various parts of the Empire Educated at the University of Edinburgh he commenced his career in the Transvaal Department of Agriculture and in 1906 entered the Indian Agricultural Service, retiring in 1923 as director of agriculture Madras In 1920 Mr Sampson made a tour in Cochin China and Cambodia to study coco nut and cotton cultivation, and after his retirement from India he worked for a time in Nyasaland for the Empire Cotton Growing Corporation Mr Sampson s appointment at Kew was made in connexion with the grant from the Empire Marketing Board for the promotion of the economic development of the Empire, and his work at Kew has been devoted to this end In addition to giving advice on crop improvement and on the introduction of plants of economic importance to correspondents from all parts of the Empire Mr Sampson has paid visits, at the request of the Colonial Office to British Guiana, British Honduras the West Indian Colonies and East and West Africa to study their economic resources He has recently published a List of the Cultivated Crop Plants of the British Empire (*Kew Bull* Additional Series 12 1936)

Sir Geoffrey Evans, C I E

MR SAMPSON S successor as economic botanist is Sir Geoffrey Evans who is retiring from the post of principal of the Imperial College of Tropical Agriculture Trinidad Sir Geoffrey was educated at Cambridge and was on the staff of the University Agricultural Department before entering the Indian Agricultural Service in 1906 He retired in 1923 as director of agriculture Bengal Afterwards Sir Geoffrey worked in Australia Fiji and New Guinea as director of cotton culture under the Empire Cotton Growing Corporation and was appointed principal of the College in Trinidad in 1927

Mr O T Faulkner, C M G

THE governing body of the Imperial College of Tropical Agriculture Trinidad has appointed Mr O T Faulkner to the post of principal of that College in succession to Sir Geoffrey Evans It is difficult to suggest the name of anyone better qualified to fill this appointment Mr Faulkner has had a ripe and varied experience of tropical and subtropical agriculture in its many and varied phases He first saw service abroad as mycologist to the Rubber Growers Research Association in Malaya, and after working there for two years was in 1914 appointed to the Indian Agricultural Service as deputy director of agriculture in the Punjab In 1921 he resigned from this Service to take up the appointment of director of agriculture Nigeria For his valuable work in this capacity where he defined the agricultural policy of the country and built up a most efficient Department he was made C M G in 1928 In 1936 he was transferred to Malaya as adviser on agriculture which post he now relinquishes to become principal of the Imperial College of Tropical Agriculture As this College is responsible for the training of all recruits for the Colonial Agricultural Service the post of principal is a most responsible and important one Mr Faulkner was born in 1890 and took his Natural Sciences Tripos at Cambridge in 1911 with first class honours and in the following year took his diploma in agriculture

Scientific Theory and Publicity

THE strictures on the methods of the B B C in relation to certain broadcasts dealing with archæological subjects, with which Prof Gordon Childe prefaced his presidential address to the Anthropological Section at the Cambridge meeting of the

British Association, has once more raised a perennial problem in scientific discussion, which is of no little public interest The methods of the B B C must be above the suspicion of propagating error, especially in relation to the advance of scientific discovery Unfortunately, the field of research to which Prof Childe refers has been in the past the happy hunting ground of the irresponsible theorist In certain branches of archæological investigation the apparent familiarity of the terminology and subject matter—the character and purpose of objects of everyday use in the life of the past, and the inferences as to cultural and racial contact to be drawn from them—not only lend themselves to speculation, but also the more startling and sensational the exposition, the more readily it commends itself as matter likely to be of interest to the public to those who control the machinery of publicity the lay Press and organizations, of which the B B C is the most important, engaged in the unofficial education of the public The obvious remedy that the B B C should be advised by a committee of scientific men, and that other organizations and the lay Press should consult expert opinion in order to eliminate the danger of error, is open to the imputation of stifling progress in favour of orthodoxy The only remedy is full and free discussion without favour, after an impartial statement of controversial points at issue

Jupiter's Satellites

POSITIONS of the newly discovered Satellite X are available from July 6 to August 1, but the interval is too short for the computation of an orbit with any degree of certainty A preliminary investigation, however, suggests that the object is at a distance of about 7 million miles from Jupiter, its motion being direct Whether it is just inside the orbit of VI or outside that of VII is open to doubt, but further observations will enable computers to decide this point Observations of Satellite XI are available from July 30 to August 1, but it is impossible to compute an orbit from such data From the figures it is conjectured that the body cannot be less than 10 million miles from Jupiter, and so it certainly lies outside VII, but there is nothing at present to show that it does not lie outside IX

THESE preliminary investigations were made by Dr M Davidson, who assumed, in the computation of the orbit of Satellite X, that this was practically circular While going to press a Harvard Card announces that two different orbits for Satellite X have been computed the results of which have been communicated by Prof E I Yowell, Cincinnati Observatory The figures in round numbers are as follows The first orbit, which indicates that the motion of the satellite is direct, has a very high eccentricity, 0 6362, the semi major axis being 5,900,000 miles This implies that the satellite makes its closest approach to its primary at a distance of 2,150,000 miles, its greatest distance being 9,650,000 miles The other orbit shows an eccentricity 0 6207, motion retrograde, and the semi major axis 18,310,000 miles If this be correct, the satellite would approach Jupiter to a distance of 6,945,000 miles, and would recede to 29,675,000 miles, the time to complete a revolution being more than 2¾ years The fact that two such diverse orbits can be deduced from the same data shows the great difficulty, as already pointed out, of attaching much importance to the elements which are based upon a short time interval

Inland Ice Field in Alaska

A **BULLETIN** of the National Geographic Society of America announces that an expedition under the auspices of Harvard University and of the National Geographic Society, and under the leadership of Mr Bradford Washburn has made, during the course of aeroplane flights, the important discovery of a vast inland ice field in Alaska The ice is hemmed in by a coastal range of mountains with peaks reaching 10 000–19 000 ft above sea level This range stretches from the Copper River Valley above Cordova to the Alsek River Valley in the Yukon Most of the ice lies athwart and to the west of the Alaska–Canada boundary line where it turns north to the Arctic Ocean The ice thus forms a barrier to land communication between the south panhandle of Alaska and the major part of the territory in the north It is stated that the ice field covers a stretch of territory 235 miles long It is in effect so extensive as to constitute an ice reservoir which provides the source of large outflowing glaciers, including the Bering and Malaspina glaciers the immense size of which—they are 30 and 50 miles wide respectively—is now accounted for This part of Alaska (which possesses the conditions favourable to glacier formation—namely, high altitude, low temperature and high precipitation) thus contains the largest known ice fields outside the polar regions It is a remarkable feat that an expedition of only four men should have succeeded in photographing 1,500 square miles of territory in a country peculiarly difficult of access They have also carried out geological work in the St Elias Range

Solar Activity and Radio Communication

IN the speech made by the Postmaster General, Major Tryon, at a luncheon of the Newcastle-on-Tyne Chamber of Commerce, he announced that the Post Office, after consultations with the American telephone authorities, is constructing a special radio-receiving station to combat the intense sunspot activity which is expected to interfere seriously with world radio communications in 1940 The long distance international radio telephone services are mainly operated on short wave lengths, and are found to be particularly susceptible to serious interference at periods of great sunspot activity This has been proved by the graphs at short wave reception stations, and the connexion between solar flares causing sunspots and fade-outs and magnetic disturbances has been clearly established Approximately, they appear to follow an eleven-year cycle, a disturbance being due in 1940, and owing to the enormous increase in the long distance telephone traffic, engineers are doing their utmost to prevent disorganization of the traffic at that period

THE British Post Office and the American telephone authorities have decided that the best way to obviate the effects of sunspot activity is to adopt a new technique for the reception of short wave transmissions A number of receiving aerials will be suitably spaced in the direction of the incoming signals The Post Office has issued a statement giving an ideal reception station It would accommodate six receivers for twelve circuits and sixteen separate aerials erected so as to face America Very stringent conditions are laid down for an ideal site for the station It must be at least two miles long, a quarter of a mile broad, the length being in the direction of America It must be flat and reasonably damp It should be remote from roads carrying motor traffic and yet be a reasonable distance from London to keep the cost of the land lines low The present Post Office receiving station at Baldock does not even approximately satisfy these conditions The Cooling Marsh at Rochester nearly fulfilled the required conditions and this has been selected It is expected that the new station will be in use early next year, and that even under very bad conditions it will be possible to maintain a satisfactory commercial telephone service

New Metallurgical Laboratories at Sheffield

SIR WILLIAM BRAGG opened the new Sir Robert Hadfield Metallurgical Laboratories at the University of Sheffield on September 15 The laboratories mark the first stage in a scheme of development of the University for which an appeal was issued two years ago Sir Robert Hadfield contributed generously in response to the appeal and as a mark of appreciation of this and his many other benefactions to the University, and particularly the Department of Metallurgy, the laboratories have been named after him, and a commemorative plaque in the main laboratory was unveiled by Sir William Bragg The following telegram was sent to Sir Robert Hadfield 'Members of the University and others assembled at the inauguration of the Sir Robert Hadfield Metallurgical Laboratories send you hearty greetings They remember with gratitude your continuous generosity to the University, and regret your absence from this ceremony They send you best wishes for a speedy recovery to health.' The University of Sheffield is unique among the universities of Great Britain in that it confers degrees in metallurgy as distinct from degrees in science, these were established so long ago as 1907 The new laboratories will be used primarily for teaching, but research work will also be carried out In his address, Sir William Bragg referred to the relation of science to industry, and said that although they may be forced together by circumstances, a metallurgical school, like the restraining constituent in an alloy which prevents separation of the components, holds theory and practice together and gives the industry strength and adaptability

International War on Locusts

THE Fifth International Locust Conference held at Brussels at the end of August was attended by delegates from more than twenty countries The great economic importance of the problem was emphasized by the results of a statistical inquiry organized by the International Centre for Anti Locust Research in London The information collected from the majority of the countries suffering from locusts and grasshoppers showed that the average cost of these pests to the world amounts to not less than 15 million pounds per annum Discussions at the Conference were centred mainly round the necessity of establishing permanent organizations for the supervision of the original centres of locust outbreaks with a view to the prevention of such outbreaks in future An agreement was reached by the various delegations that such organizations should be established without delay and financed on an international basis This decision was made possible by the extensive investigations carried out during recent years by an international team of entomologists surveying some of the most inaccessible parts of Africa and Arabia There is every hope that the recommendations made by the Conference will be adopted and acted upon by the Governments concerned and that the control of locusts by the prevention of the swarm formation will become an accomplished fact

Launch of the *Graf Zeppelin*

A NOTABLE example of the progress of aeronautical science was provided by the launching on September 14 of the new German airship L Z 130, to which Dr Hugo Eckener gave the name *Graf Zeppelin* The launch is described as having been carried out with precision and the great ship took to the air perfectly It will be recalled that, on a similar occasion two years ago, the *Hindenburg* took about half an hour to rise and then twice lurched downwards before her height was brought under control It may therefore be inferred that the designers and constructors have now at their disposal much more complete knowledge as to the factors which influence the stability and behaviour of large airships and that the new vessel is thereby the more assured of a successful career On the first of her acceptance trial flights she cruised for a period of eight hours and made a good landing at the Loewenstadt Military Aerodrome Hydrogen was used as the lifting medium When the *Hindenburg* was wrecked at Lakehurst in the United States, it was stated that hydrogen would not in future be used As, however, helium is practically unobtainable outside America, the engineers have devised a method whereby it is claimed that the main risk is largely eliminated This is associated with the necessity for releasing free hydrogen as the load diminishes due to the consumption of the fuel, but by arranging for the storage of the water formed during combustion, they have provided the necessary ballast so that the ship's height can be controlled with little or no recourse to wastage of hydrogen The motive power is supplied by four Daimler Benz engines, each of more than

700 horse power which give the ship a cruising speed of about 80 m p h In length she is 803 ft — slightly less than the *Hindenburg*—but her hydrogen capacity of 7 062 000 cub ft is fully 25 per cent greater

Iron Age Settlements in Wiltshire

THE investigations by the Prehistoric Society of iron age sites near Salisbury have completed for the time being the examination of the settlement at Odstock which began on June 12 under the direction of Mr C W Phillips honorary secretary of the Society About half of the six acre site has been dug and the remainder will be examined next year The settlement is dated at about 200 B C and as anticipated was found to have been occupied by a small agricultural community growing wheat oats barley peas and beans though traces of wheat only have been discovered Apparently they farmed on an extensive scale As much as fifty tons of grain was stored in a single season Light is thrown on their methods in the report of the recent investigation (*The Times* Sept 6) Many pits for the bulk storage of grain were found within the settlement enclosure but as storage in damp conditions would encourage the grain to sprout it was first toasted in large ovens before being placed in the pits Remains of ovens used for ordinary cookery have also been found as well as quantities of pottery iron knives bone implements etc There is evidence that among the domestic animals were pigs cows and goats and a large number of horses of a small type Some time after the first occupation the settlement was surrounded by an enclosing bank and ditch which were in no sense a fortification Within this enclosure in addition to the pits already mentioned were a large house a timber structure forty five feet in diameter with an external veranda a second which was thirty feet in diameter and a number of other timbered erections

IF the inference as to the character and purpose of the fragments of pottery from the pits is well founded and they are the remains of ovens which had been used for drying corn this is the earliest link in a chain of evidence for a practice which can then be traced in Britain from about 200 B C down to modern times In *Antiquity* of September Dr Cecil Curwen refers to the practice of drying corn in kilns in the island of Lewis comparing the kilns with the corn drying furnaces found in some Romano British settlements in southern Britain Mr O G S Crawford in a note quotes evidence for the practice in the west back to at least the sixth century of our era while Dr Curwen adding that the kilns seem to have been a product of Roman culture in western Europe states that so far as he was then aware they did not occur in Britain before the latter part of the Roman period The evidence from the Wiltshire settlement is thus of considerable interest as a possible instance, considerably earlier in date and not of Roman origin, of a practice with a prolonged history of cultural continuity

Prehistoric Scottish 'Temple'

FURTHER progress is reported in the excavation of the prehistoric temple at Clydebank Dumbartonshire of which Mr Ludovic Mann is in charge The central area of the site in which are a large number of inhumed and cremated interments of the stone and bronze ages is estimated to have a diameter of six hundred feet A recent discovery reported in *The Times* of September 19 is that of the remains of a circular walled enclosure 43 feet in diameter at a distance of 219½ ft from the main centre which is now in course of being uncovered In the walling to the north west has been found a large rectangular stone In contact with this was a fallen pillar stone This seems to have formed part of an altar like structure The pillar stone had been shaped and on cleaning showed traces of what are described as serpentine devices in black and red pigments—a discovery which if confirmed by further examination appears to be unique in British archæology At a distance of 55 ft from the centre of this stone ring and on the same radius as the stone and pillar was another large fallen upright stone Many of the finds on this site which include five different types of pottery are said to be unique in character and technique A large number of socket holes have been discovered which contain decayed and carbonized wood apparently largely of oak The temple seems to have consisted to a great extent of earthworks of which the layout is indicated by the postholes along the margins Traces of a circle of nineteen large equidistantly set monoliths have been detected at a distance of 129 ft radius from the main centre It is evident that this site is of considerable importance and complexity and that careful excavation and planning will be necessary before its true character and purpose can be determined

Economic Use of Water-Power

UNTIL recently engineers considered that when both water and fuel power were available then it was best to develop all the water power first and then use steam as an auxiliary source of power In designing many recent power stations this procedure has almost been reversed The steam station is built first the overhead costs being much cheaper then when the load gets large and it would otherwise be necessary to provide reserve generators and equipment to take the main load a beginning is made with the water power station which is mainly used to help with the peak load and so avoids the necessity of purchasing reserve generators In the preliminary report published in 1934 of the National Resources Board, set up by the United States Government it is stated that the great technical advantage of water power plants is that they can be turned on for a few hours work and then turned off again without much loss In the present technical regime, their function is mainly that of a supplementary source, used to carry peak loads for brief periods During the rest of the time the load is carried by the more economical fuel burners In the August number of the *BEAMA* journal, H E M Kensit points out that quite small water power stations possessing good 'pondage' or moderate storage facilities can be economically developed to several times their continuous capacity in order to take the peak loads of fuel power systems. In Great Britain the Water Power Sources Committee reported in 1921 that there were 250,000 kilowatts of continuous power available. The modern view is that where small water-powers are used, they should be 'over-developed' by providing reservoirs so that they could take both the base loads and the peak loads. There are several electric-power schemes in America which take full advantage of the utility of the storage capacity of water-power in reservoirs when combined with steam stations.

Science and Culture

THE August issue of *Science and Culture*, published in Calcutta under the auspices of the Indian Science News Association as "a monthly journal of natural and cultural sciences", includes several important contributions and is in every way a credit to all who are concerned with its production. In the leading article on social implications of science, support is given for the movement represented by the committee on science and its social relationships of the International Council of Scientific Unions and the new Division of the British Association, and it is suggested that the Indian Science Congress Association should discuss the subject in a plenary session at the forthcoming meeting at Lahore. Sir James Jeans's lecture on the origin of the planets, delivered during the visit of delegates of the British Association to India, is published in the issue; and among the subjects of other interesting articles are: electrical charge distribution in thunderclouds, chemical composition and nutritive value of bananas, and recent advances in the study of plant growth hormones. The speeches made by Sir John Simon and Sir William Bragg at the anniversary dinner of the Royal Society on November 30, 1937, are reprinted in full from the *Notes and Records* of the Society, the first issue of which appeared in April last, together with notes on the foundation and history of the Society from the same publication.

The late Lord Rutherford

THE *Transactions and Proceedings of the Royal Society of New Zealand*, vol. 68, June 1938, contains an obituary notice and photograph of Lord Rutherford, signed "E M.", doubtless the work of his old research student at Manchester, Dr. E. Marsden, who is now head of the N.Z. Department of Scientific and Industrial Research. There are about thirteen pages of biography written by one who well knew and admired Rutherford. Then follow nine pages of bibliography, listing about three hundred publications of books and papers by Lord Rutherford. This has been carefully compiled by Dr. C. M. Focken, Beverly-Mackenzie lecturer in physics at the University of Otago.

Earthquakes in Italy and in New Zealand

THE Central Office of Meteorology and Geophysics at Rome has recently issued its catalogue of *macrosismi*, or sensible earthquakes, for the year 1935 (*Boll. Sismico, anno* 1935). The total number known is 134, or about one third of the average number (412) for the forty years 1891–1930. Their intensity, also, was much less than usual; more than half were so slight that they were not able to shake doors or windows, and only one, with its origin in Etna, approached destructive strength, several houses in Acireale being slightly injured. The seismological section of the Dominion Observatory at Wellington has issued a somewhat less detailed report on the New Zealand earthquakes of 1936 (*Bulletin* No. 125; 1937). From this, we learn that the number of sensible earthquakes was 125, less than half the average (264) for the preceding twelve years, but nearly the same as the average number (122) for the eight years excluding 1929–32, in which many after-shocks of the great earthquakes of 1929 and 1931 occurred. Five of the shocks were of intensity 6 (Rossi-Forel scale), that is, none could be ranked as a destructive earthquake. The epicentral regions (Buller River and Hawkes Bay) of the two earthquakes referred to seem to have resumed their normal activity.

Renewed Seismic Activity in Greece

ATHENS has again been disturbed by strong earth tremors but no damage has been done in that city. The epicentre of the shock is reported to have been to the north-east of the city, and is probably the same as that of July 20 and also July 27. The most recent shock was registered on seismograms in London at about 3 a.m. on September 18, and does not appear to have been any more intense than that of July 20.

Belgian Red Cross Exhibition

THE Belgian Red Cross is organizing a popular scientific exhibition to be held in the Egmont Palace, Brussels, on October 1–30. It will be entitled "L'Homme" and will comprise the following groups: (1) movement (bones, muscles, nerves); (2) blood vessels and circulation; (3) respiration and voice; (4) foods and digestive organs; (5) thought and sensation; (6) special senses; (7) the part played by glands; (8) transparent organs; (9) the man of glass; (10) individual and public health. Further information can be obtained from Croix Rouge de Belgique, 80 rue de Livourne, Brussels.

A Catalogue of Rare Books

IN addition to works on English and European literature, the fine arts and a selection of important new books, a catalogue recently published by Bernard Quaritch, 11 Grafton Street, London, W.1, contains an annotated list of works on natural history including books from the library of Baron Bouck, early medicine and surgery from the library of Sion College, and the exact and applied sciences. Among the numerous works on natural history may be mentioned the German text of J. Hübner's "Collection of Exotic Butterflies" (1806–1841) described as "an extremely fine and complete copy of the greatest entomological work ever produced," "Rippon's monograph on bird-wing butterflies (1898–1906), of which not more than thirty copies were completed, and Dresser and Sharpe's history of the birds of Europe (1871–1896). The most notable works on medicine and surgery in the catalogue are the first quarto edition of Sir Thomas Elyot's "Castel of Helth" (1541), the first edition of Gerard's "Herball or Generall Historie of Plantes" (1597) and the first edition of Harvey's "De Motu Cordis" (1628). Among the old works on the exact and applied sciences figure the first edition of Cocker's "Arithmetik" (1678), Billingsley's translation of Euclid's "Elements of Geometrie" (1570), Watson's translation of Bernard Palissy's "Learned Dialogue Concerning Waters and Fountaines" and Zahn's work on contemporary optics (1702).

Speed Records

ON September 15, the world's speed record on land was raised to 350·2 m p h by Mr. John Cobb at the Bonneville Salt Flats, Utah. The car used was a 2,500 h.p Napier-Railton The previous record was 345·59 m p.h. set up by Captain G E. T Eyston in his car *Thunderbolt* (see NATURE, Sept. 3, p 430). On September 16, Captain Eyston regained the world record from Mr. Cobb with the *Thunderbolt*, attaining an average speed of 357·5 m p.h Sir Malcolm Campbell set up a water speed record of 130·91 m.p h. on September 17 at Lake Hallwil, Switzerland, in his motor-boat *Bluebird*.

North-East Coast Institution Engineering Awards

THE Gold Medals of the North East-Coast Institution of Engineers and Shipbuilders given for papers read during the session have been awarded as follows: Engineering Gold Medal to G J. Lugt, of the Werkspoor Company, Amsterdam, for his paper on "Diesel Varia"; Shipbuilding Gold Medal to Prof. F. Horn, of the Technische Hochschule, Berlin, for his paper on "Measurement of Wake"; M. C. James Gold Medal to Dr. T. Swinden for his paper on "Special Steels and their Application to Engineering and Shipbuilding". The Thomas Fenwick Reed Gold Medal, for the member of the Institution not more than thirty years of age who, among entrants for the medal, shows the greatest evidence of ability to take a share in the control of industry, has been awarded to John Hindmarsh. Mr Hindmarsh was for some time in the employment of Michell Bearings, Ltd., before obtaining his Whitworth Scholarship, when he went to King's College, London; he is now employed by Messrs. Swan, Hunter and Wigham Richardson, Ltd., Neptune Works, Walker, Newcastle-on-Tyne. The Institution is giving two new scholarships this session (each of £100). These have been awarded to Harry Chilton, an apprentice of the North-Eastern Marine Engineering Co. (1938), Ltd., and a student at Sunderland Technical College; and Thomas Corin, an apprentice ship draughtsman in the employment of Messrs. Swan, Hunter and Wigham Richardson, Ltd., Wallsend-on-Tyne, for study at King's College, Newcastle-on-Tyne.

Announcements

DURING the forthcoming winter, Mr. H. V. Garner, the guide demonstrator of the Rothamsted Experimental Station, and other members of the staff, will be available for lectures on the Rothamsted experiments to agricultural societies and similar bodies. All communications regarding lectures should be addressed to the Secretary, Rothamsted Experimental Station, Harpenden, Herts.

PROF ALFRED KÜHN, director of the Kaiser-Wilhelm Institute of Biology, Berlin, Dr. Hugo Hassingen, professor of geography at the University of Vienna, and Dr Hans Ahlmann, professor of geography at Stockholm, have been elected members of the Prussian Academy of Sciences in the physico-mathematical class

THE Child Welfare Information Centre of the League of Nations has issued a useful analysis of reports received by the Secretariat from thirty-seven countries on the legislative and administrative measures that have been taken or have been under consideration during the year May 1937 to May 1938 with reference to any aspect of child welfare (London: Allen and Unwin, 3s)

THE Child Guidance Council has awarded fellowships in psychiatry of the value of £300 and tenable for a year to Drs. Allen G. Crisp, Kenneth Soddy and Rosalind Vacher for half-time work at the London Child Guidance Clinic, 1 Canonbury Place, Islington, N.1.

THE New York banker, Mr. W. Childs, has left Yale University ten million dollars for cancer research.

THIRTY radio coast stations of the United States are provided with a medical man to give advice to passing ships.

THE London County Council has accepted a tender for £72,135 for building work in connexion with the erection of its new antitoxin establishment at Carshalton, which will afford valuable opportunities for research.

THE Ministry of Health with the collaboration of the Department of Health for Scotland and the National Fitness Council has arranged a permanent Health Exhibition which is being shown at the British Empire Exhibition and will be sent on to towns throughout Great Britain.

THE sixth Argentine Congress of Medicine, which will be held at Cordoba on October 16–21, will consist of three sections devoted respectively to biology, internal medicine and surgery.

THE twenty-fifth French Congress of Social Hygiene will be held at the Bordeaux Faculty of Medicine on September 30–October 2 under the presidency of M. Georges Risler. Further information can be obtained from Alliance d'hygiène sociale, 5 rue des Cases, Paris.

J. & A. CHURCHILL

Well Illustrated ★ ***SEVEN NEW BOOKS*** ★ *Lucid Text*

NEW (2nd) EDITION. 101 Illustrations. 21s.

CHEMISTRY OF THE PROTEINS

By DOROTHY JORDAN LLOYD, M.A., D.Sc., F.I.C., Director of the British Leather Manufacturers' Research Association; and AGNES SHORE, B.Sc., A.I.C., Demonstrator, Physiology Department, London (Royal Free Hospital) School of Medicine for Women.

With an Introduction by SIR FREDERICK GOWLAND HOPKINS, O.M., M.B., D.Sc., F.R.C.P., F.R.S.

"Although English books dealing with the chemistry of proteins are not lacking, the present work stands alone in aim and in scope. It contains a synthesis of knowledge such as has not hitherto been attempted in this domain."—The Introduction

A NEW BOOK. 21 Illustrations. 7s. 6d.

AN INTRODUCTION TO INDUSTRIAL RHEOLOGY

By G. W. SCOTT BLAIR, M.A., Ph.D., A.I.C., Head of the Chemistry Department, National Institute for Research in Dairying, University of Reading; Part-time Lecturer in Colloids, Sir John Cass Technical Institute, City of London.

With a FOREWORD by EUGENE C. BINGHAM, A.B., Ph.D., D.Sc.

This volume, being the first one of its kind, should find a useful place in all industrial laboratories.

NEW (2nd) EDITION. 41 Illustrations 21s.

THE CHEMICAL ANALYSIS OF FOODS

A Practical Treatise on the Examination of Foodstuffs and the Detection of Adulterants

By H. E. COX, Ph.D., D.Sc., F.I.C., Analytical and Consulting Chemist; Public Analyst for the Metropolitan Borough of Hampstead and the County of Cornwall

Thoroughly revised and brought up to date, including much new matter. Particular attention has been given to methods for the determination of preservatives, of metallic impurities, fluorides and substances such as ascorbic acid, and enzymes.

NEW (14th) EDITION. 130 Illustrations. 18s.

Clowes and Coleman's

QUANTITATIVE CHEMICAL ANALYSIS

Edited and Revised by D. STOCKDALE, Ph.D., A.I.C., University Lecturer in Chemistry, Cambridge, and J. DEXTER, B.Sc., A.I.C.

For this edition the type has been completely reset and a considerable part of the text has been rewritten. The general arrangement of the volume remains unchanged, and its primary object is to serve as an intermediate textbook.

A NEW BOOK. (To be published in 7 Vols.) Vol. I. 50 Illustrations. (Ready in October.) 8s. 6d.

VITAMINS AND VITAMIN DEFICIENCIES

By LESLIE J. HARRIS, Ph.D., Sc.D., F.I.C., Nutritional Laboratory, Medical Research Council and University of Cambridge.

With a Foreword by SIR FREDERICK GOWLAND HOPKINS, O.M., F.R.C.P., F.R.S.

Vol. I. Introductory and Historical—Vitamin B_1 and Beri-Beri.

"I can strongly recommend the book to all students who desire acquaintance with the present position and outlook in the field of vitamins, and believe that the specialist will welcome an admirable summary of the facts available to-day and a bibliography fully up to date."—The Foreword.

A NEW BOOK. 4 Plates and 33 Text-figures. 12s. 6d.

BIOCHEMISTRY FOR MEDICAL STUDENTS

By W. V. THORPE, M.A., Ph.D., Reader in Chemical Physiology, University of Birmingham.

This volume is an endeavour to supply the student of medicine or dentistry with those Biochemical facts that he will require especially.

A NEW BOOK. 87 Illustrations. 12s. 6d.

ELEMENTARY ANATOMY AND PHYSIOLOGY

By JAMES WHILLIS, M.D., M.S., F.R.C.S., University Reader in Anatomy, Guy's Hospital Medical School.

With a Foreword by Prof. T. B. JOHNSTON, M.D., Ch.B.

Correlates structure and function, and emphasises the essential inter-dependence of Anatomy and Physiology.

104 Gloucester Place, London W.1

LEITZ

LEITZ microscope objectives are famed throughout the world on account of their high degree of correction and their unvarying quality—attainable only by the most exacting methods of control at every stage of production. LEITZ objectives are equally well known for their comparative immunity to tropical conditions. Full use is made of new kinds of glass as these become available in a constant endeavour still further to improve the performance of LEITZ objectives and to ensure their continued superiority.

Achromatic objectives for routine clinical investigations.

"Fluorite" objectives— recommended for dark-ground microscopy and photomicrography on account of their excellent spherical and chromatic correction.

Apochromatic objectives for critical research and highest resolving power.

LEITZ achromatic objectives specially selected for their freedom from polarising properties can be supplied at a slight extra charge.

Write also for particulars of LEITZ OBJEKTOL, the new immersion fluid.

E. LEITZ (LONDON) LTD., 20 MORTIMER ST., W.1

THIS is the first up-to-date general text of fluid mechanics, catering specifically for the hydraulic engineer. It presents in systematic detail the fundamental principles of fluid motion and their application to various phases of hydraulic engineering. Emphasis is placed upon sound physical analysis of actual flow phenomena, in order to provide the engineer with more dependable methods of approach than empirical hydraulics can afford.

The presentation is new. Although some of the subject-matter is to be found in foreign texts, the basic material is explained in more simple mathematical terms, and places in the hands of the hydraulic engineer sound physical methods of approach long since adopted in other professions—in particular in the fields of aeronautics, structures, and elasticity and strength of materials.

The new material includes : A comprehensive study of the flow net and its application ; modern conceptions of fluid turbulence ; rapidly varied flow in open channels ; sediment transportation ; and wave motion.

Fluid Mechanics for Hydraulic Engineers

LABORATORY CHRONOGRAPH

This instrument may be used to record simultaneously the occurrence of any three events, which can be arranged to make or break an electric circuit. Time signals at the rate of 50 per second can be recorded to an accuracy of 0·01 second. The Chronograph may be driven direct from a small electric motor, or a suitable speed reduction gear can be supplied. A six-pen Chronograph is also made.

Full details are in LIST 100-N. May we send you a copy?

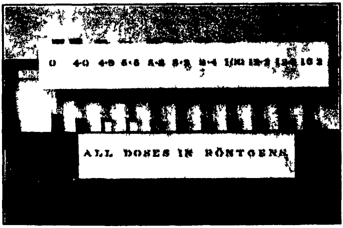
Effect of Increasing Doses of X-Radiation on Colloidal Gold

SOME time ago, in a communication from this Department[1], it was shown that a steadily increasing exposure to X radiation produced alternate increases and decreases in the electrokinetic potential of certain colloid particles The colloid used at the time (a dilution of Aquadag' in water) is peculiarly stable, and at no stage were there any signs of coagulation It was thought possible that with a more sensitive colloid the decrease in potential at the minima of the curve might be sufficient to bring the colloid to its flocculation point, and at my suggestion Dr Liebmann and Mr Jones have been working with certain pure gold sols

After irradiation in a quartz dish by measured doses of X radiation, the specimens of the sol were transferred immediately to well cleaned pyrex test tubes, and allowed to stand for a few hours As will be seen from the attached photograph, specimens of the sol which had been exposed to doses of 4 9 and 5 5 röntgens were completely coagulated, and that exposed to a dose of 5 8 röntgens very largely so On the other hand, specimens of the same sol exposed to larger doses (8 2–12 8 r) show no signs of precipitation The last tube (13 2 r) shows slight sedimentation, indicating the onset of a new coagulation dose



The results are completely reproducible, for the given sol, and measurements with the ultra microscope show that the doses producing coagulation are, in fact, those which produced the greatest decrease in the electrokinetic potential of the particles The photograph illustrates very vividly the interesting fact that, at any rate for certain colloidal solutions, a comparatively small dose of X-radiation may produce complete precipitation, while a dose of twice the amount leaves the sol apparently unaffected A further feature of interest is the very small quantity of radiation required to produce the effect

It is hoped to publish further details of the measurements shortly

Structure of Age-Hardened Aluminium-Copper Alloys

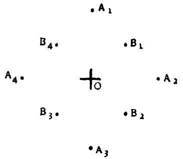
WE have made X ray diagrams of aluminium copper alloys (5 per cent Cu) age hardened at various temperatures (25°–200° C), the samples were composed of large crystals and the radiation was made monochromatic by reflection by a crystal In a previous paper[1], we described a new phenomenon which appeared in these diagrams streaks of various length issuing from the centre, which we attributed to the reflection of X rays by planes We have shown that these planes are parallel with the 100 planes of the crystal of solid solution and, moreover, that they are of small dimensions (100–400 A) We assumed therefore that these planes were composed of groups of copper atoms without making any hypothesis about the disposition of the atoms within those groups

Continuing the study of these alloys (among other things we have made use of molybdenum radiation besides that of copper) two other peculiarities were noticed

(1) From the very intense spots produced by the X ray reflection by the 111 100 110 planes of the solid solution, one or two straight streaks of varying dimensions and of very weak intensity issue As to the spots 100 one is directed towards the centre, the other is perpendicular to it As for the spots 111, 110, on the contrary, they may be inclined to the central radius

(2) A number of distinct spots of extremely weak intensity appear, for which the crystals of the solid solution cannot be responsible By orientating a given crystal so that the primary beam is parallel with an edge of the cube, the diagram which appears on a plate perpendicular to the beam is shown schematically in the figure below The streaks in the centre are due to the groups of atoms included in the planes perpendicular to the plane of the figure, and the distance OA is equal to the distance from one spot 100 of the aluminium crystal to the centre, and the spots B_1, B_2, B_3, B_4 are in the middle of the lines A_1, A_2

We may therefore regard this diagram as the diffraction figure of a two-dimensional lattice, which would be identical with a plane 100 of an aluminium crystal



Likewise, the study of the variation of the streaks described in the previous paragraph with the crystal orientation shows that these traces may be imputed to diffraction by such a two-dimensional lattice

These new experiments enable us to determine more closely the structure of the plane groups which we have described, it seems that the copper atoms should gather in patches in the 100 planes of the solid solution during hardening and should thus produce three rectangular systems of two-dimensional lattice of small extent

[1] *C R*, **206**, 1641 (1938) and *C R*, **206**, 1972 (1938)

THE results reported by M Guinier are of interest to us as similar work has been in progress during the past two years in this Laboratory, and we have arrived at virtually the same conclusions as those given by M Guinier A paper describing the results of my experiments was communicated to the Royal Society on May 10, and a brief abstract has already appeared[1]. Pending the publication of the full account, the following summary may be of interest.

The 'two-dimensional' diffraction effect, to which M. Guinier refers, produces a series of elliptical streaks on the Laue photographs of single crystals of an alloy of aluminium with 4 per cent of copper aged at room temperature The accompanying photograph is of a crystal aged for six months at room temperature, orientated with a (110) direction parallel to the X-ray beam. The elliptical streaks make their appearance an hour after quenching the alloy; at first they are broad and faint, and in the course of a week, during which the alloy is hardening spontaneously, they become stronger and narrower, indicating that the area of the regions rich in copper is increasing.

If the alloy, age-hardened at room temperature, is heat-treated at 200° C., the first effect is a rapid reduction of hardness; the Brinell number falls from a figure of about 100 to 60 in ten minutes. At the same time the streaks disappear almost completely. Further heat-treatment leads to a rise in hardness to about 100 in a few hours; during this period the streaks reappear, but they are now quite narrow, showing that the plates of copper-rich metal are of considerable extent, of the order of 10^3 A, but still very thin, less than 10 A If the heat-treatment is continued, the hardness falls slowly and the streaks on the Laue photographs begin to break up into ill-defined spots, which on further heat-treatment become increasingly sharper, and ultimately a new set of Laue spots, indicating the presence of well-developed crystals of a second phase, makes its appearance.

In addition to the metallurgical interest of these observations, the results suggest that application of X-ray methods may throw light on the details of the mechanism of chemical reactions in the solid state.

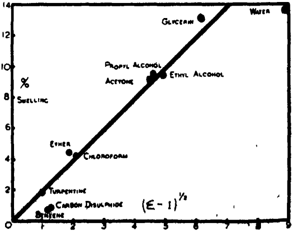
The Swelling of Birch Wood

M. HASSELBLATT[1] has measured the maximum linear tangential swelling of birch wood in a number of different liquids. An analysis of his results shows that they appear to fit the relation

$$s = a\sqrt{\varepsilon - 1},$$

where s is the swelling measured as an extension per



unit length, a is a constant of proportionality, ε is the dielectric constant (or S I C) of the liquid in which the wood is swollen

The extent of the agreement is shown in the accompanying graph

The above equation is in accord with W Sementschenko s theory of absorption[2] if we assume that the mechanical strain energy per unit volume of swollen wood is proportional to the energy produced on absorption of molecules from the liquid by all the cellulose micelles in a unit volume of wood

The strain energy per unit volume is $\frac{1}{2}Es^2$, where E is a mean value of Young s modulus of the birch the absorption energy is proportional to $(\varepsilon - 1)$ Assuming proportionality between these two quantities, we see that the above equation at once results

A Concentration and Measurement of Atmospheric Ozone

Prof F A Paneth and Mr J L Edgar are to be congratulated on having devised a new and ingenious chemical method of measuring both the ozone and nitrogen peroxide in the London atmosphere[1]

It is interesting to note that their measurements agree with those which I obtained as a result of five years continuous measurements at both Plaistow and Upminster by means of an entirely different chemical method[2] My mean figure for the ozone in spring air was given as $1\,2 \times 10^{-6}$ vol per cent whilst that of Prof Paneth and Mr Edgar is given as $1\,1 \times 10^{-6}$

Prof Paneth and Mr Edgar s criticism that the older methods of analysis were not specific and did not distinguish between ozone and nitrogen peroxide does not apply to my own method which was specific I passed half the air through a tower filled with fine crystals of copper sulphate (which completely destroys the ozone but does not affect the nitrogen peroxide) and compared it with the other half containing both the ozone and the nitrogen peroxide The ozone is obtained by difference

There is an interesting point regarding the nitrogen peroxide in the atmosphere which my measurements of both town and country air brought out Nitrogen peroxide is not a normal constituent of country air Like the sulphur dioxide and ammonium chloride in town air (which I also measured) all three are the products of the combustion of coal The percentage of all three increases in the winter In country air near London the percentage of all three is trifling unless the direction of the wind brings them from London The percentage of ozone is independent of the direction of the wind

[1] NATURE 142 112 (July 16 1938)

[2] *J Soc Chem Ind* 168T (March 28 1930)

IN the note on atmospheric ozone[1] we confined ourselves to a brief outline of our method leaving the discussion of the great number of other chemical attempts at ozone measurements to an intended fuller publication there of course due credit will be given to the very interesting paragraphs dealing with atmospheric ozone determinations in Dr W C Reynolds s paper on London air[2]

It has frequently been assumed that the presence of ozone in air is sufficiently proved by the observation that part of its oxidizing property is quickly destroyed by contact with various reagents Dr Reynolds made use of this effect for a quantitative ozone evaluation by determining the oxidizing power of air before and after this treatment Whether such a method of measurement should be called specific for ozone is a question of terminology but we are sure that Dr Reynolds will agree that it is safer to collect the ozone in a pure state to prove its identity by its absorption spectrum and then to titrate it in a range of concentration in which the potassium iodide method has been found to be satisfactory For highly diluted ozone this method of titration is liable to various errors and the simultaneous titration both of ozone and nitrogen peroxide in such dilutions would have to be investigated very thoroughly before full confidence could be placed in it

It is not obvious from Dr Reynolds s paper whether such preliminary work has been done but apparently he himself does not consider the nitrogen peroxide titration with potassium iodide as very satisfactory since he employs quite a different method when this gas is to be measured Further if anyone intends to apply such a differential method for the ozone determination we should not recommend copper sulphate for the destruction of the ozone content of air according to our experiments even in a slow current of gas this substance is likely to leave part of the ozone unaffected while manganese dioxide which has been used for the same purpose by Usher and Rao[3] or charcoal destroys it completely

Nevertheless it may well be that the figures obtained by Dr Reynolds as well as many of the other figures published by chemists on the ozone content of air were essentially correct, it can scarcely have been a mere coincidence that by crude chemical methods, at least the right order was found long before any spectroscopic measurement was available The trouble was not that these methods necessarily gave wrong results but rather that their reliability could not be checked and that there were not infrequently big discrepancies between results which seemed equally trustworthy It is, in fact, our hope that a much simpler chemical method than the one described by us may be found to be sufficiently exact for meteorological purposes but there is scarcely a better way for deciding this than by comparison with a method which by isolating and identifying the atmospheric ozone is free from the obvious shortcomings of the older ones

Neutrons and the Origin of Life

WHEN in early days of the development of the earth its surface was covered with an aseptic solution of various organic compounds, these did not react in the same way as they would have done if certain enzymes, colloids and other complicated substances had already been present[1] The very first impetus to further development had to be given from molecules containing, for example, carbon and nitrogen in certain combinations One possible way of combining nitrogen and carbon not yet discussed in this connexion, may be found in conjunction with certain nuclear reactions, also prevalent in Nature at those early days

By the action of cosmic rays or hard γ rays from radioactive matter present in the ocean, the deuterium of the heavy water, contained in the ocean water, will produce neutrons These neutrons are slowed down in the water and will react with the nuclei of atoms in the molecules dissolved in the water Thus, for example, a heavy carbon atom in an already existent carbon chain compound should be transformable (through a short lived radioactive carbon isotope) into a stable nitrogen atom by expulsion of a β particle

$$^{13}_{6}\mathrm{C} + ^{1}_{0}n \rightarrow ^{14}_{6}\mathrm{C}^{*} \rightarrow ^{14}_{7}\mathrm{N} + {}_{1}\beta$$

If the molecule in which this reaction takes place *is not destroyed by the recoil or by the* β particle the new nitrogen atom may give rise to a new rather unexpected molecule containing a carbon nitrogen link and capable of new reactions In the same way also a phosphorus atom may be generated from a silicon atom and so on

Even the direct action of very hard γ rays on oxygen[2] is capable of producing a stable nitrogen atom (with mass number 15) through a short lived radioactive oxygen isotope

$$^{16}_{8}\mathrm{O} + \gamma \rightarrow ^{15}_{8}\mathrm{O}^{*} + ^{1}_{0}n$$
$$^{15}_{8}\mathrm{O}^{*} \rightarrow ^{15}_{7}\mathrm{N} + ^{0}_{+1}e$$

Thus various complicated organic molecules containing, for example, carbon nitrogen may have originated in a way rather different from ordinary chemical reactions and will perhaps have influenced the evolution of organic matter, eventually leading to the first primitive forms of living matter, no longer present on earth

Condensation Coefficients of Mercury Halides

USING the method of Alty[1], we have measured the coefficients of condensation (f) of the compounds mercuric chloride, bromide and iodide A hemispherical cap of these salts was deposited by sublimation on the end of a glass tube which could be heated internally by boiling turpentine The temperature of the cap surface was measured by a fine thermocouple while the salt evaporated in a high vacuum The quantity of salt evaporated per unit time and area (M_1) was determined by weighing the deposit on a surrounding glass tube immersed in liquid air By calculating the maximum rate of evaporation (M_2) from the formula of the kinetic theory of gases

$$M_2 \quad \frac{0\ 0584\ \sqrt{M}}{t}\int^{t}\frac{P}{\sqrt{T}}\,dt \text{ gm /cm}^{2}\text{ sec ,}$$

where P is saturated vapour pressure (mm mercury), M is molecular weight, t is time of evaporation, T is absolute temperature, one finds $f = M_1/M_2$

The mean of the results of three or four runs for each substance is as follows

$HgCl_2$	$HgBr_2$	HgI_2
0 76 ± 0 1	0 64 ± 0 1	0 53 ± 0 1

For calculating M_2 the saturated vapour pressures P were extrapolated from the formulæ given in the Critical Tables The extrapolated values seem to be a little too small as compared with single direct measurements[2], and for this reason the coefficients f may be close to unity This means that each molecule striking the solid surface condenses at once The mercury halide molecules being linear have no dipole moment, and so this result is not inconsistent with Alty s empirical rule that the coefficients f for non polar molecules are near unity

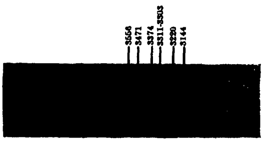
Probable Dissociation of Nitrogen Molecules in the High Atmosphere

KAPLAN[1] recently succeeded in exciting, in the after glow of nitrogen, a line, λ 3471 A, that probably corresponds to the forbidden transition $^2P \rightarrow {}^4S$ of NI Theoretically it is very interesting and curious to see that this line is emitted under relatively high pressure, at the same time as the Vegard Kaplan bands, which are themselves forbidden

Here, however, I wish chiefly to direct attention on the application of this beautiful experiment to the knowledge of physical conditions of the upper atmosphere Indeed, as Kaplan points out, Dufay[2] and Gauzit[3] mentioned the presence of an intense radiation at a wave length λ 3471 A in the spectrum of the night sky, new observations, made by me, confirm very clearly the existence of this radiation and its intensity, as it is easy to see on the accompanying spectrum Probably we have here the line of NI, as Kaplan suggested two years ago[4]

The two arguments which prevented acceptance of this attribution have now disappeared First, the



ULTRA-VIOLET SPECTRUM OF THE NIGHT SKY

line λ 3471 A has been produced in the laboratory Further, while the dissociation during the day by absorption of ultra violet light from the sun is certainly very slight any other process seemed impossible , we thought that the energy for excitation of the light of the night sky—which does not exceed 7 electron volts—is not sufficient to dissociate the nitrogen molecule But this energy of dissociation was not accurately known , the value (9 0 volts) accepted a few years ago is now recognized as too high , the value adopted to day[5] is 7 34 volts We can consequently accept the dissociation of nitrogen molecules

In a recent paper Bernard[6] shows that a radiation at λ 3471 A is also present in the spectrum of diffuse auroras where the Vegard Kaplan bands are particularly intense This is an interesting confirmation of the probable presence of metastable *N*I atoms in the high atmosphere But Bernard s paper requires two comments

(1) Vegard and his collaborators probably observed the line λ 3471 A in the aurora they did not separate it from the second positive band near 3469 A the intensity attributed to this band is evidently too high

(2) The line λ 5206 A which corresponds to the $^2D - ^4S$ transition of NI, has not yet been recognized in the night sky , but its existence in the spectrum of the aurora was pointed out by V M Slipher and L A Sommer[7], who suggested its origin and mentioned that the line had been observed[8]

In conclusion, I propose seeking the λ 5206 A line in the spectrum of the night sky by a right choice of photographic plates and studying the λ 3471 A radiation of the night sky by the interferometer method, in order to ascertain for certain the existence of nitrogen atoms in the high atmosphere

Angular Distribution of Electron Pairs

A NUMBER of experiments have been made on the angular distribution of electron positron pairs liberated by a beam of γ rays, but the results, where it is possible to compare them, do not seem to be in agreement It is therefore of interest to see what the theory predicts, and in the following a short account is given of the results obtained by a rigorous treatment of the problem The method used is an extension of that given by us[1] to find the total number of pairs created So far, the calculations have been made for Z (atomic number) = 84, $h\nu = 5\ mc^2$, and $Z = 50$, $h\nu = 3\ mc^2$ and $5\ mc^2$, where $h\nu$ is the energy of the γ ray

Denoting the *average* angles made by the direction of the electron and positron with the direction of the γ ray by θ_e and θ_p respectively, and the *average* angle between the pair by γ, the following results were obtained.

(1) θ_e, θ_p and γ decrease with increasing energy of the γ ray For particles of definite energy, the formula given by Bethe and Heitler[2] for the number of electrons of energy E_e emitted at an angle θ_e

$$\Phi(\theta_e)d\theta_e - \frac{\theta_e\, d\theta_e}{(\Theta^2 + \theta_e^2)^2} \qquad \Theta \qquad \frac{mc^2}{E_e},$$

is not valid for such low energies The values found for θ_e θ_p and γ when $Z = 84$ are about twice those given by the above formula ($h\nu - 5\ mc^2$)

(2) θ_e is slightly greater than θ_p This is to be expected since the average energy of the positron is greater than that of the electron This is in qualitative agreement with Grosev and Frank[3], who find for krypton $\theta_e - 33°$, θ_p 30°

(3) θ_e, θ_p and γ increase slowly with Z It is easy to show that the angular distribution is independent of Z to the first order (Born approximation), but for large Z the electrostatic forces on the particles become important and these must be responsible for the increased values of θ_e, θ_p and γ noted in (1) The strongest evidence in support of this would seem to be Alichanian s experiments[4] on lead, with $h\nu$ 14 mc^2 He found γ to be about 65°, as compared with 48° in krypton[3] for a considerably lower energy ($h\nu$ 5 mc^2) Similar results have been obtained by Jelepov (ref 3 p 52 footnote)

The calculations involved in the use of the accurate wave functions are extremely laborious particularly the evaluation of γ the angle between the pair For purposes of comparison with the theory it is therefore advantageous to have experimental results for θ_e and θ_p It is hoped to publish fuller details and results shortly

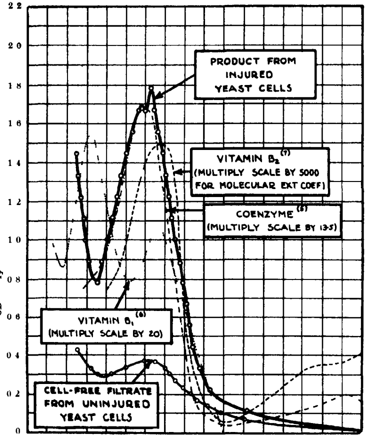
Chemical Nature of Proliferation-Promoting Factors from Injured Cells

WE have published investigations indicating that yeast[1] and animal cells[2] injured by ultra violet light and other means produce factors (intercellular wound hormones')[3] which are apparently released by injured, but living, cells into the intercellular fluid and stimulate the proliferation of normal cells Spectrographic and chemical studies indicate that the active materials from yeast contain nucleic acid derivatives, as previously suggested[4]

The 'wound hormones' were produced by prolonged, low intensity, full ultra violet irradiation of yeast in isotonic salt solution or distilled water Cell-free Berkefeld filtrates from irradiated and non-irradiated suspensions were assayed in yeast growth experiments The biological potency and extinction at 2600 A were much more marked in the filtrates from irradiated suspensions, and the potency and 2600 A extinction in various samples were closely parallel

As shown on the accompanying graphs, the spectrum of the 'wound hormone', or factor from injured cells (obtained by photographing the spectrum of the filtrate from irradiated yeast with filtrate from non irradiated yeast in the comparison cell) is characterized by a marked maximum at 2600 *A* and a minimum at 2360 A similar to the spectra of nucleic acids and their derivatives[5] On irradiation of the filtrate from injured cells, the extinction at 2600 A decreases and that at 2360 A and on the long wave leg of the curve increases as in adenine, guanine etc[6] Of absorbing components of nucleic acids, the spectrum least resembles that of uracil or cytosine Guanine is suggested by the broadness of the curve and adenine by the 2600 A maximum The spectrum is markedly different from that of vitamin B_1 [7] It lacks the long wave maximum of vitamin B_2 [8] It is similar to that of coenzyme[9]



Filtrates from both irradiated and non irradiated suspensions contained nitrogen and phosphorus but not halogens or sulphur (negative lead acetate nitroprusside and Sullivan reactions before and after sodium fusion) Both contained pentose (Bial test) but apparently not desoxypentoses (Kiliani test[10]) The Thomas[11] β napthol test gave a blue ring with both materials and a non uniform brownish colour with the Thomas[11] tryptophane reagent Negligible reducing activity was shown with Benedict s solution, and substantial freedom from protein by the biuret test Both materials gave positive murexide[12], Kossel[13], and diazo[14], and negative Weidel[12] and Wheeler Johnson[15] tests The positive reactions were more marked with the filtrates from irradiated suspensions Slight turbidity or opalescence was obtained from phosphotungstic, picric, and meta phosphoric acids No precipitate formed with $HgCl_2$ Contrary to previous indications[4], no positive colour reactions[16] could be obtained for pyridine even after boiling The active materials gave *p*H values of about 5 5 (glass electrode) in concentrations of 0 5 to 1 5 mgm per c c They were soluble in water and 50 per cent alcohol slightly soluble in 95 per cent and absolute alcohol and insoluble in ether and petroleum ether Their activity was not reduced by autoclaving at 20 lb for 15 minutes

A correlation of the spectrographic and chemical data shows the presence of phosphorus pentoses guanine and adenine Uracil cytosine pyridine and vitamins B_1 and B_2 are not indicated and yeast nucleic and adenylic acids seem to be ruled out by the Thomas[11] tests Of related substances resemblance is closest to cozymase[17] or coenzyme[9] The presence of guanine and the apparent absence of pyridine suggest that though similar to it the wound hormone is not identical with coenzyme or cozymase

Mutation of the Blood-Group Genes

THE current theory of the mutation of the blood group genes postulates the appearance of gene *A* by mutation in one or more sites in the Europe-Asia land mass, and a similar appearance of gene *B* in India and in Africa.

There is little doubt that the mutation giving rise to gene *A* and *ipso facto* to group *A*, must have been a replacement of, or a change in, gene *R*, but the same certainty does not hold for the mutation of gene *B*. Gene *B* may have been a replacement, in one form or another, of gene *R* or of gene *A* or of both genes. Each of these three possibilities implies a different pre-mutation distribution of the genes in the races concerned.

If gene *R* alone was susceptible to *B* mutation, then the pre-mutation frequency of *R* in a race undergoing this change must have been equal to the sum of the post-mutation frequencies of *R* and *B*, and the frequency of gene *A* would be unaltered by the phenomenon.

If gene *A* alone was susceptible, then the frequency of gene *R* would be unaffected by the change, and the pre-mutation frequency of *A* would be equal to the sum of the post-mutation frequencies of genes *A* and *B*.

If both genes were liable to change, then, had the mutation affected all the susceptible genes, the present frequency of gene *B* would be 100 per cent, and for less complete changes the effect of the mutation is given by the equation

$$A = \frac{a}{1 - b}$$

where A is pre-mutation frequency of gene *A*, *a* is post-mutation frequency of gene *A*, *b* is post-mutation frequency of gene *B*.

This means that in the Hindu, if *R* alone were susceptible, the pre-mutation frequency of *A* must have been 0·149, if *A* alone were susceptible, this frequency must have been 0·440, and if both were susceptible, the frequency of *A* prior to mutation must have been 0·210.

The fact that there are no races showing gene *B* without some gene *A* suggests that the presence of *A* is a *sine qua non* to the appearance or mutation of *B*. It follows from this that *B* mutation was a change in gene *A* alone.

If this be the case, then the pre-*B* mutation frequency of *A* will show a maximum in the centre of the Europe-Asia land mass, as opposed to the minimum in the same place shown by the post-*B* mutation frequency of *A*. This is an attractive idea as it would imply a single mutation of gene *A*.

In what races other than the Hindu is there direct evidence of *B* mutation? It is generally accepted that there must have been such a change in Africa, but the site of this change is generally considered to have been West Africa, mainly because the Yoruba and the Senegalese show a biochemical index of less than unity. However, these peoples could have obtained their present distribution as a result of the mixing of other races in Africa. The only races having *B* in Africa about which this cannot be said are the pygmies and the Egyptians. These peoples each show a high proportion of both *A* and *B*, and could have given rise one to the other, but this seems unlikely on other grounds. They could not have received their gene distributions by the crossings of any other known races, even including the Hindu.

If we accept the conception that *B* mutation was a change in gene *A* and not in gene *R*, then the distributions of these races could not have arisen from any extant race or races by mutation, but their pre-*B* mutation frequency of gene *A* must have been considerably higher than that shown by any modern races, and in fact, higher than that shown by the pre-*B* mutation phases of any other people.

This implies one of two possibilities: either there was a mutation of *A* in Africa, or Africa was invaded by peoples having a very high proportion of *A*. When one bears in mind the extreme bastardization of the modern Bush people, it seems likely that they too, in their purer forms, must have had a similar proportion of *A*. Now did these various peoples, Bush, Pygmy and Egyptian, receive their *A* from the same source, and was this source an African *A* mutation, or was it the main mass of mankind?

Finally, there is a third, and very interesting possibility, namely, that Africa was the site of the main *A* mutation, and that peoples outside Africa have obtained their *A* from that continent.

Pleistocene Site in the Malay Peninsula

IT was to be regretted that until recently no artefacts of Pleistocene age had been found in the Malay Peninsula, and particularly so because of the relationship of the peninsula to the now sunken Sundaland which formerly joined Sumatra, Java and Borneo to the mainland of Asia.

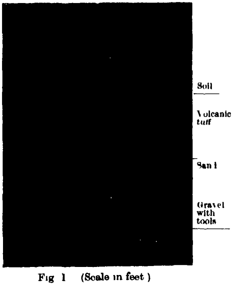

Fig. 1. (Scale in feet.)

Acting on a suggestion of Mr. E. S. Willbourn, director of the Geological Survey, F.M.S., I visited the Kota Tampan Rubber Estate which lies on the west side of the Perak River about three and a half miles south of Lenggong, Upper Perak. On this estate is a deposit of volcanic tuff overlying a bed of sand and gravel which itself rests on laterite. The site lies just below the 250 ft. contour and is probably an old terrace of the Perak River. Since there have been no recent volcanoes in Malaya, a foreign origin had to be supposed for the tuff, specimens of which were kindly examined by the Netherlands Indies Vulcanological Survey in Bandoeng, who reported that it probably came from "the big Toba eruption', which was the origin of Lake Toba in Sumatra Fig 1 shows a stream cut section of the deposits, but the underlying laterite cannot be seen

In this and two other nearby gravel beds were found stone tools, typical specimens of which are shown in Fig 2 The majority are made from pebbles of quartzite and most of them are unrolled or only slightly rolled They comprise (*A*) Chopper with just enough flaking to make an edge This is the commonest type (*B*) Chopper, of very fine grained rock, the exact find spot is shown by the cross in Fig 1 (*C*) Hand axe, triangular section, rolled the only specimen found (*D*) Hand axe, the butt has been flaked to reduce the size of the tool

The characteristics of these tools are that they are made from pebbles with the minimum flaking on one side only, and the cutting edge is always made by the meeting of a flaked surface with the unworked natural pebble skin

The other types consist of flakes worked up into end scrapers, hollow scrapers and points, together with a large number of pebbles used as hammer stones The latter tools would seem to show that the place was a workshop and perhaps even a dwelling site

As yet not enough specimens have been found to warrant detailed comparison with other cultures, and dating is not possible on palæontological grounds since no fossils were found There does, however, seem to be an undoubted kinship with the Pajitan culture described by von Koenigswald from central Java[1], but it differs from it in the complete absence of bilateral flaking and in the greater amount of original pebble surface which is preserved It may therefore be an earlier phase of the Pajitan culture The commonest type (Fig 2A) is very much like a Pre-Stellenbosch tool from South Africa illustrated by van Riet Lowe[2]

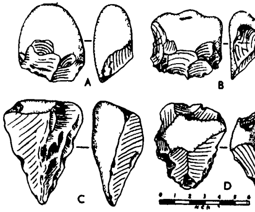

Fig 2

It is hoped to carry out further excavations in the near future, and in the meanwhile I propose the name *Tampan Culture* to describe the tools from this, the first Pleistocene archæological site to be found in the Malay Peninsula

Dry Crossing of the Nile

THROUGH the co operation of Dr Alexander Cruickshank, senior medical inspector of the Equatorial Province of the Sudan, and of my son, Lieut Colonel F O Cave, I am able to give some recent particulars of Wayland s crossing, or the dry crossing of the Nile Dr Cruickshank visited it last Easter and took photographs of it, one of which is reproduced herewith The width of the river is about 80 yards, and the width of the crossing from its upstream to its downstream edge is approximately 250 yards

WAYLAND S CROSSING EASTER 1938 LOOKING DOWN STREAM WIDTH OF RIVER APPROXIMATELY 80 YARDS DEPTH OF CROSSING APPROXIMATELY 250 YARDS

In places the accumulated vegetation exceeded 10 feet in thickness but at the edges it was loose and thin in places, and one of Dr Cruickshank s porters fell through But away from the edges and presumably in some parts at the edges it was thick enough for elephants to cross, for recent elephant spoor was found On the surface there was a thick ash deposit left after grass and papyrus had been burnt It would appear from Dr Cruickshank s account that there are no signs of the crossing breaking up at present

Distribution of the Polychæte *Ophelia cluthensis* McGuire

Ophelia cluthensis was described in 1935 by McGuire[1], who obtained her specimens from Millport in the Clyde, and more fully in 1938 by Brown[2] It occurs in a narrow zone of sandy beaches just below high water mark neaps, frequently to the extent of several hundred to the square metre Besides being recorded from the Firths of Clyde and Forth, Wohlenberg[3] records its presence at Sylt, Germany Specimens obtained by Fauvel[4] at Saint Vaast, France, were described by him as young *O limacina* but are considered by Brown to be probably *O cluthensis*

As a result of recent shore collecting I have now to record the species from South Wales and Ireland The Welsh specimens were obtained from a small area of the beach at Lavernock in the Bristol Channel, about four miles along the down channel coast from Cardiff The salinity at high water at this point varies from 20 per mille in winter to 28 per mille in summer The Irish specimens were obtained from a sheltered bay at Falcarragh, Co. Donegal, about six miles east of Bloody Foreland The salinity of the water here is affected, particularly at low water, by a stream of freshwater. At one station 1,100 specimens per square metre were counted At both places the sand was of fine grade with a small quantity of silt

[1] Early Palæolithic Stone Implements from Java *Bull Raffles Mus* Ser B 1 No 1 1936

[2] The Geology and Archæology of the Vaal River Basin Geological Survey Union of S Africa *Mem* 35 Pl VIII No 1

I am obliged to Dr A C. Stephen for confirming my identification, and for the information that the Welsh animals are quite typical, but that the Irish specimens show a certain amount of variation In both cases the animals are small, the largest being only 8 mm in length, so that these variations are probably due to immaturity.

The addition of these two records lends support to Dr. Stephen's opinion that *O. cluthensis* is considerably more common than the previous records suggest It seems certain that this species has been frequently overlooked or dismissed as a juvenile form

Connexions of the Pterygoquadrate in the Tadpole of *Philautus variabilis* (Anura)

WHILE examining the chondrocranium of Ranid and Rhacorphorid (Polypedatid) genera of frogs, the connexions of the pterygoquadrate with the cranium were found to vary considerably. It is well known since the time of Parker[1] and Gaupp[2] that in the anuran larvæ, the pterygoquadrate gains attachment with the cranium normally in three regions, namely, an anterior ligamentary or, in the majority of cases, a cartilaginous quadrato-ethmoidal connexion, the second connexion is in the posterior orbitotemporal region, called the processus ascendens, which bears definite relationship with the three branches of the Vth cranial nerve. When the tadpole undergoes metamorphosis, this larval connexion is lost (say in the case of *R. fusca* larva (*S temporaria*) 29 mm, de Beer[3]) and the adult is without one There is no anuran larval form described where, in the larval stages prior to metamorphosis, the absence of a processus ascendens is described. The last connexion is the oticus one; the posterior portion of the pterygoquadrate unites with the dorsal wall of the otic capsule over the cranioquadrate passage. This connexion, however, may be absent from some tadpoles.

Now, with regard to the genera which I have examined, *Philautus variabilis* Günth (tadpoles kindly identified by Prof. C. R. Narayan Rao) needs special mention. I have examined the sectional views of at least two tadpoles of each of the stages measuring 22 mm. and 24 mm. (head and trunk 10 mm.) and 31 mm. (head and trunk 11 mm.) in all of which the posterior limbs have not appeared. All these tadpoles belong to premetamorphic stages. While the anterior connexions of the pterygoquadrate with the cranium are normal, the sections of the posterior orbitotemporal region do not show the presence of the connexion of a processus ascendens palatoquadrati with the pila antotica or an oticus connexion with the otic capsule, there being a little connective tissue between the posterior portion of the pterygoquadrate and the cranium, and so far as is known to me the absence of both these connexions in the larval anura is not recorded This is a remarkable feature in *P. variabilis*, and if the processus ascendens connexion has broken down as early as the stage studied, then it is an excellent example of developmental acceleration or heterochrony If, on the other hand, the connexion is not established at all, which I think is more probable, then *P. variabilis* is the first anuran larval form where both the processus ascendens and oticus connexions are wanting

Further study of the development of the cranium in this and allied forms is engaging my attention, and the result will be published elsewhere

My thanks are due to Prof A Subba Rau for helpful criticisms

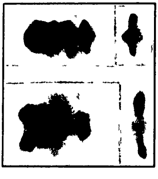
Differentiation of Heterochromatic Regions during Meiosis

HETEROCHROMATIC regions have been revealed in the somatic cells of a large number of plants and in certain animals during the metaphase by many investigators They are usually situated around the centromeres and at the distal ends One of the characteristic properties of the heterochromatic regions is the intensive absorption of hæmatoxylin and other stains Genetically, they are poor in genes in *Drosophila* and are usually called 'inert regions'.



The chromosomes have usually a spiral structure during the meiotic metaphase This is characteristic for both heterochromatic and euchromatic regions Differentiation of heterochromatic and euchromatic regions in pure species during the meiotic metaphase is technically more difficult than in some species hybrids, where one of the parents has longer chromosomes, obviously with a larger amount of heterochromatic substance than the other The accompanying illustration shows two meiotic metaphases in side view and two single bivalents from two other meiotic plates of the amphidiploid *Nicotiana glauca* × *N Langsdorffii* Both single bivalents have darker regions at the portions turned towards the poles, where the centromeres are obviously situated The bivalents at the left side of both metaphase plates are darker than the right (lighter) pairs of each plate The former have probably more heterochromatic substances than the latter Each of the lighter bivalents of these two plates has two chiasmata, their centromeres, directed towards the poles, are surrounded with small heterochromatic (darker) portions

Points from Foregoing Letters

A PHOTOGRAPH is submitted by Prof J A Crowther showing the effect of increasing doses of X radiation on colloidal gold The photograph shows that, whereas the sol is completely precipitated by doses of 4 9–5 5 röntgens, larger doses of 8–12 8 röntgens leave the sol completely stable

In X ray diagrams of age hardened aluminium copper alloys, A Guinier finds diffraction spots produced by two dimensional lattices, suggesting that the copper atoms form small plane groups, where they maintain a regular disposition G D Preston reports a similar effect, observed in Laue and oscillating crystal photographs during the process of age hardening of an alloy of aluminium with 4 per cent copper He ascribes it to the segregation of copper atoms of relatively high scattering power on widely separated (100) planes of the aluminium lattice

Dr N A de Bruyne finds that the maximum linear swelling of birch wood is related to the dielectric constant of the swelling liquid by an equation which has a simple theoretical interpretation

Dr W C Reynolds points out that the percentage of ozone in London air found by Prof F A Paneth and J L Edgar, namely, 1 1 × 10^{-6} vol per cent, agrees with that which he obtained during five years measurements by an entirely different specific chemical method Prof Paneth and Mr Edgar comment on a few essential differences between their method and those previously employed for the determination of atmospheric ozone

Dr J Tandberg suggests that nuclear reactions may have influenced the development of organic matter in the ocean in primeval times Organic molecules may on rare occasions have had a carbon or oxygen atom transformed into nitrogen as an impetus to new and rather unexpected reactions, resulting in organized systems with colloids, leading to primitive forms of living matter

The coefficients of condensation of mercury chloride, bromide and iodide are calculated by F Metzger and Dr E Miescher to be 0 76, 0 64 and 0 53 respectively, using the formula of the kinetic theory of gases Owing to uncertainty in the extrapolated values of the saturated vapour pressure the authors infer, however, that the condensation coefficients may be close to unity, which would mean that each molecule striking the cold solid surface condenses at once

Prof J Gauzit states that his new observations of the spectrum of the night sky confirm the presence of an intense λ 3471 A radiation, which probably coincides with the line recently excited by Kaplan in the high pressure nitrogen afterglow Recent determinations reduce to 7 34 volts the energy of dissociation of nitrogen molecules, and thus dissociation in the high atmosphere is probable The line λ 5206 A, which corresponds to the transition $^2D - {}^4S$ of NI, has already been observed in the auroral spectrum

By calculations involving the use of accurate wave functions, J C Jaeger and Dr H R Hulme estimate that the average angles made by the electron and the positron with the beam of gamma rays by which they are liberated, and also the average angle between the electron and positron, decrease with increase in energy of the gamma rays and increase slowly with the atomic number of the atom involved The average angle for the electron would be slightly greater than for the positron

The chemical nature of the factor producing cell proliferation, formed by the action of ultra violet light upon yeast cells, and generally when cells are injured (wound hormones) has been investigated by Prof J R Loofbourow, E S Cook, and Sister M M Stimson Its absorption spectrum is similar to that of cozymase or coenzyme but the presence of guanine and the apparent absence of pyridine suggest that it is a different substance

Assuming that the gene responsible for the *B* blood group reaction arose from a mutation of a gene responsible for the *A* blood group reaction (or admitting, at any rate, the presence of *A* before the presence of *B*), Dr R Elsdon Dew discusses the probable place of origin of the genes in the light of the present geographical distribution of the various blood groups among African peoples

The discovery of artefacts of Pleistocene age in gravel underlying volcanic tuff at Tampan, Malay Peninsula, is reported by H D Collings

Records of the distribution of *Ophelia cluthensis* McGuire in Wales and Ireland are added by C B Rees to previous records from Scotland, Germany and France

Dr L S Ramaswami reports that in the cranium of two tadpoles of *Philautus variabilis* he has been unable to find either the processus ascendens or the oticus connexions and, unless the connexions had broken down at an unusually early stage, this would be the first case of anuran larvæ in which those connexions are absent.

Research Items

Stone Age Cultural Succession in Southern Rhodesia

A ROCK-SHELTER on the Nyazongo Mountain, twenty miles to the north of Penhalonga and ten miles from the eastern border of Southern Rhodesia, has been excavated by Mrs C. Martin with the view of ascertaining whether a sequence comparable to that established by A. L. Armstrong for the Bambata Cave also occurs throughout Mashonaland, and, if possible, of determining the predecessor of the Wilton culture on the eastern border. A trial trench dug in October 1936 was extended in 1937 to a total measurement of nine feet by ten. Mrs Martin's report is supplemented by technical reports by the late Father P. Stapleton, dealing with the implements, and by Mr L. H. Wells, dealing with the pottery (Queen Victoria Memorial Library, Salisbury, *Occasional Paper* No. 1, 1938. Pp. 18. 5*s*. net). The existence of two stone age industries was established, Bambata and Wilton. The lower is characterized by broad flakes of both greenstone and quartz and 'points' in both materials. This occupies the third and fourth foot of the excavation. It predominates in the fourth foot, and in the third is mixed with Wilton. It does not appear in the higher levels, but is found below the fourth foot level and under the ledge in front of the cave. This confirms the conclusion that this is the earliest industry of the shelter. The points show that it is a Bambata industry, though it is not the latest phase of that industry. The upper culture is Wilton. It occurs first in the fourth foot, more than fifty specimens being counted from that horizon; but from the third foot some one hundred and fifty were recovered, and from the first two feet more than three hundred. There is no break between the industries. Though they were not contemporaneous, the interval between them cannot be long. Ground axes belong to the Wilton horizon, though not to the earliest part. The custom seems to have come in during the Wilton occupation. The fragments of pottery found in abundance in the uppermost foot and occasionally in the second foot fall into four or rather three groups, which may be resolved into two types, belonging either to the previously known 'pit-circle' people, or the later Manyika inhabitants.

Recent Botanical Exploration of China

PROF. H. H. HU has recently reported upon his botanical collections in China since 1920 (*J. Roy. Hort. Soc.*, 63, Pt. 8, August 1938). Although many garden plants of proved excellence are of Chinese origin, that country must hold many more botanical or horticultural treasures. A beautiful new species, *Sinojackia xylocarpa*, was, for example, found in a suburb of Nanking. A rich harvest of new species is cited in the paper, and several of them are figured upon very clear lithographs. Prof. Hu's collections have been mainly from south-western Yunnan, and three distinct elements have been recognized in the flora, namely, the Burmese, the Indo-Chinese and the endemic. The Indo-Chinese elements link the Yunnan flora with that of Kwangtung, Kwangsi, Hainan and Formosa. Species of the genera *Camellia*, *Adinandra* and *Eurya* are the chief endemic plants, but a number of new rare genera are also represented. Many Burmese genera are found in Yunnan but not elsewhere in China.

History of Rhubarb Cultivation

THE use of rhubarb for medicinal purposes is of considerable antiquity, for the Chinese herbal of Pen-King mentioned its corrective properties as early as 2700 B.C. Miss D. M. Turner has made a study of the economic significance of various kinds of rhubarb from that date until the present time (*J. Roy. Hort. Soc.*, 63, 8, August 1938). Though known in classical times, it was not until the thirteenth century that roots of the 'rhapontic' rhubarb were brought to Europe by Marco Polo. Herbals of the seventeenth and eighteenth centuries mentioned several kinds, and the plant attained culinary popularity about 1750. Miss Turner's paper considers the history, taxonomy, hybridization and varieties of *Rheum rhaponticum*, *R. palmatum*, *R. undulatum*, and other species. Forcing of the plant during winter was apparently discovered by accident at Chelsea in 1817, and the history of rhubarb forcing in the south West Riding of Yorkshire makes interesting reading. The climate of this region, though unsalubrious for man and many other organisms, is completely adjusted to the needs of rhubarb grown for forcing.

Compounds of Divalent Europium

PRESENT knowledge of the compounds of divalent europium makes it probable that in this state the metal behaves like an alkaline earth metal, intermediate in properties between strontium and barium. G. Beck and W. Nowacki (*Naturwiss.*, 26, 496, 1938) report experiments on the preparation and crystal structure of the sulphide and fluoride of divalent europium which support this view. To prepare europium fluoride, EuF_2, the trivalent fluoride, EuF_3, was reduced in a stream of hydrogen at a red heat. An impure europium sulphide, EuS, was obtained by heating the oxide Eu_2O_3 in a current of hydrogen sulphide. It was pure violet in colour, but contained some oxysulphide. The pure sulphide was obtained by heating europium sulphate, $Eu_2(SO_4)_3$, in a current of hydrogen sulphide. It was brownish-violet in colour and was pyrophoric when gently warmed. Efforts to make the oxide EuO were unsuccessful. The crystal structures of the sulphide and fluoride were determined by the usual methods. The sulphide EuS has a lattice of the sodium chloride type with $a = 5.957 \pm 0.002$ A. The ionic radius of Eu^{++} obtained from this is 1.24 A. Europium fluoride, EuF_2, has the fluorite structure. Comparison of the lattice constants with those of strontium and barium fluorides shows that in this respect europium compounds approximate more closely to strontium than to barium compounds.

Study of Atmospheric Dust

P. L. FAYETTE (*Thèse de Paris*, No. 487; 1938) states that although the first work on pulmonary diseases due to inhalation of dust dates from the eighteenth century, the first scientific work on the subject did not appear until the beginning of the nineteenth century and was due to the researches of Laennec, Parent Duchatelet and Virchow. Fayette describes the following groups of dust inhalation of which may be injurious. (1) Microbial dust in which the number of germs varies according to the site, season and atmospheric conditions. (2) Dust with a local chemical action giving rise to silicosis. (3) Dust containing particles of coal or tobacco which merely causes a change in the colour of the lung without producing disease. (4) Dust containing substances such as wool, cotton, silk, pollen and drugs which give rise to a number of allergic diseases. The campaign against dust which is more advanced in Great Britain and the United States than in France is of special importance in industrial hygiene, in which medical selection and supervision of workmen exposed to the inhalation of dangerous dust are very desirable.

Atmospheric Pollution at Wellington, N.Z.

METEOROLOGICAL OFFICE NOTE NO. 19 of the Department of Scientific and Industrial Research, New Zealand, is an extract from the *New Zealand Journal of Science and Technology* in which an analysis is given by C. E. Palmer of observations of atmospheric pollution at Wellington, N.Z. They were made with the aid of a dust counter of the type designed by Owens and extend at irregular intervals over a period of four years. They are not numerous enough to give a comprehensive survey even for the limited area of Wellington in which they were made, but nevertheless afford some interesting comparisons with similar data in other towns that are less fortunate than Wellington in the matter of pollution. The apparatus provides for the sudden cooling by expansion of air already saturated with water vapour, which leads to supersaturation and the condensation of the excess on ions, hygroscopic nuclei and dust particles present in the sample of air under examination. The resulting droplets adhere to a slip of glass and can then be examined under the microscope. A table is given showing the relative numbers of different types of particle and also the accompanying meteorological conditions, the particles being classified under four main headings: (a) separate black smoke spheres large and small, the small being at or near the limit of visibility with a 1/12 in. oil immersion objective, while those distinctly visible were classified as large, (b) aggregates of smoke spheres, (c) hygroscopic crystals, and (d) glassy particles. The separate smoke spheres are much the most numerous and the glassy particles the least numerous although of relatively large size (generally 10–20 μ in diameter). The average number of particles of all kinds per cubic centimetre was 184 whereas Kidson found about 500 in Melbourne, and in London the figure is more like 10,000.

Accuracy of Meteor Data

IN a recent paper, Mr. J. G. Porter has dealt with 102 meteors doubly observed by Mr. J. P. M. Prentice and Mr. G. E. D. Alcock (*J. Brit. Astro. Assoc.*, **48**, 9, July 1938). The paths of these have been computed, and Mr. Porter has made a brilliant analysis of the data with the object of discovering possible sources of observational errors. It is well known to meteor observers, and more so to computers of their real paths, that one or more observers will frequently miss a portion of the path, either beginning or ending or both. British observers have generally aimed at recording *directions* of flight with great accuracy, and their object has usually been attained. Admittedly they often miss a portion of the beginning or ending, but this does not prevent a computer from determining the radiant, which depends upon direction and not on length of flight. Mr. Porter's paper shows conclusively that there are also small errors in direction—*errors in altitude*'—and that the end of the path is more accurately observed than the beginning, a conclusion that one would expect from the fact that when a meteor is seen its path and end can be followed with considerable accuracy, whereas its exact beginning can be recorded only when the observer is looking towards that particular portion of the heavens. As the errors are distributed at random according to the analysis, the arithmetic mean of the computed heights is the best value to adopt, and the mean deviation can then be taken as a criterion of the weight of the path. It is pointed out that the harmonic mean of the computed velocities should be used to obtain the greatest accuracy—a method adopted by Öpik some years ago—and an elementary proof is supplied for the reader. Estimates of magnitudes should, it is suggested, be given as mean zenithal magnitudes, the reduction being effected by the formula, $m = 5 \log \sec z$, where z is the zenith distance of the meteor when observed, and m is the magnitude reduction.

Origin of Binary Stars

DR. RAYMOND A. LYTTLETON has recently published a paper (*Mon. Not. Roy. Astro. Soc.*, **98**, 8, June 1938) in which he casts serious doubts on the theory of the origin of binaries by fission. A brief discussion of the fission problem is given, with reference to the work of Poincaré, Darwin, Liapounoff and Jeans, who investigated the configurations of equilibrium of a rotating mass of gravitating liquid of uniform density, especially that part of the problem which dealt with the secular stability of the pear-shaped figure. Jeans showed that this pear-shaped figure is secularly unstable, and within recent years Cartan has shown that it is also ordinarily unstable, so that once the pear-shaped series is reached, the relative motion of the parts is no longer slow and oscillatory. From this point the motion cannot be traced by a series of definitely equilibrium configurations, the system departs in an exponential manner from the critical configuration and it is possible to advance a number of general considerations indicating the result of this instability, though the motion cannot be followed rigorously. Dr. Lyttleton discusses the matter and deals with the two cases which arise for consideration. (1) The smaller body may be endowed with insufficient velocity to escape from the larger body. If, however, the smaller comes within the Roche limit, as it would do, disruption would occur. The assumption of nearly equal masses made by Jeans is inadmissible because there is insufficient angular momentum in the critical ellipsoidal form. (2) The smaller body may escape altogether from the larger—a view which is shown to be much more likely. The fission theory is unable to explain systems in which the mass-ratio is less than 3:1, and as similarity of mass is the rule rather than the exception in spectroscopic binaries, it seems that the origin of binary stars by fission must be discarded, as well as deductions from it relating to the time-scale.

Vector Maps and Crystal Analysis

By Dr. Irving Langmuir and Dr. Dorothy Wrinch

IN a series of communications, Patterson[1] and Harker[2] have introduced a new method of exhibiting the data contained in X ray photographs of a crystal with the view of facilitating the use of such data for the determination of the atomic arrangement in the crystal The essential feature of this type of analysis lies in the use of special Fourier series by means of which it is theoretically possible to construct a three dimensional 'vector' map of a crystal, regarded as a distribution in space of positive and negative point intensities, superposed upon a continuously varying volume distribution of electrons These maps represent, not the distribution of the point intensities in space, which is of course the objective of crystal analysis, but vector distances between them taken two at a time The question then arises as to how far it is possible to derive from point intensity distributions in 'vector space, S_2, corresponding point intensity distributions in 'atomic' space, S_1

Vector diagrams, that is, sections and projections of vector maps, have been constructed in a few cases including proustite[3], pyrargyrite[3], and pentaery thritol[3] Supplemented by data relating to the chemical composition, density, etc , of the crystal, they have been used in the determination of these structures Some vector diagrams have also been constructed for an insulin crystal[4]

Previous to the construction of these diagrams, a structure, namely, the cyclol cage C_2, was proposed for the insulin molecule[5] Investigations were consequently undertaken[6,7] to ascertain whether these diagrams confirm this structure or (as has been stated[4,8]) fail to confirm it, in the course of which it became clear that simple geometric arguments make it possible to go a long way towards interpreting these diagrams, and presumably other vector diagrams also, even when nothing whatever is known about the chemical composition, size, shape or density of the insulin molecule In this communication a preliminary sketch is given of the geometrical method developed in these investigations, since it appears to have a wide field of applicability in the interpretation of vector maps, whether they are derived from molecular or megamolecular lattices

We consider first vector maps which result from various simple distributions of point intensities Suppose in atomic space S_1 there are two points A, B with intensities $\pm r$, $\mp s$ respectively To construct the vector map in space S_2 of this distribution in S_1, we select any point O as origin in S_2 and erect at O vectors corresponding to the vector distances from A to A, from B to A, from A to B, and from B to B, associating with AA, BA, AB and BB, the end points of these vectors, intensities r^2, $-sr(=-rs)$, $-rs$ and s^2 respectively. We may write this result in the form

$$V(\pm rA \mp sB) \equiv (\pm rA \mp sB, \ \pm rA \mp sB) = r^2AA - srBA - rsAB + s^2B^2 \qquad (1)$$

Here the points AA and BB lie at the origin O, and since the steps from B to A and A to B in S_1 are equal and opposite, the points BA and AB in S_2 are symmetrically placed with respect to the origin We notice that points in S_2 obtained from pairs of points in S_1 with intensities of the same sign have positive intensities, those obtained from pairs of points in S_1 with intensities of opposite signs, negative intensities , also that the magnitude of the intensity at O is the sum of the squares of the intensities of the points in S_1

Now the expression on the right of (1) is the formal expansion of the expression $(rA - sB)^2$ and the generalized expression

$$V\Big(\sum_n r_nA_n\Big) \equiv \sum_n r_n^2A_nA_n + \sum_{m \neq n} r_nr_mA_nA_m \qquad (2)$$

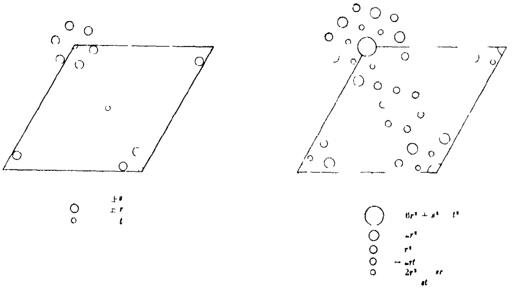
similarly gives the method of constructing vector maps for any set of point intensities in any dimensions This binomial formulation of the structure of the vector map of a set of points not only makes it simple and easy to be sure that all the requisite terms have been considered it also indicates the type of mathematical problem upon the solution of which the interpretation of vector maps depends It is essentially akin to the problem of finding a square root , indeed *interpretation of vector maps is the art of deducing the positions of n points in space S_1, from the positions of n^2 points in S_2*

To apply these ideas to crystals, we consider distributions of point intensities which are periodic Thus if in S_1 there is a one dimensional distribution, consisting of points of intensity $\pm r$ alternating with points of intensity $\mp s$ at even distances, the vector map in S_2 has the same unit cell and comprises at cell boundaries an intensity of $r^2 + s^2$ and at mid points intensities of $-2rs$

A second illustration—a two dimensional crystal in which the unit cell is rhombic—is shown in Fig 1*a* The repeating unit consists of a hexagon of points of intensity $\pm r$ at the centre of the hexagon a point of intensity $\mp s$, in addition a point of intensity $\pm t$, arranged as shown The vector map, periodic in the same unit cell, is shown in Fig 1*b* It contains points with intensities $2r^2$, r^2, $2r^2 - 2rs$, $2rt$, $-2st$ (In the figures, relative intensities are indicated by the areas of the circles They have been drawn for the particular case in which in S_1 r $-s$ t = 8 -6 3, so that the intensities in S_2 are in the ratio $2r^2$ r^2 $2r^2-2rs$ $2rt$ $-2st$ 32 16 8 12 -9)

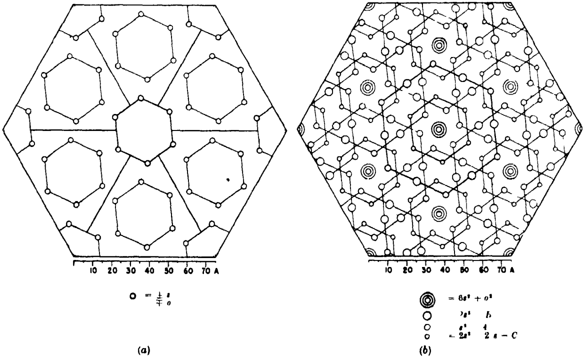
A third example relates to a three dimensional crystal in which the rhombohedral cell contains one molecule consisting of points of intensity $\pm s$ at the corners of an octahedron and a point of intensity $\mp o$ at its centre The molecules are arranged with one trigonal axis along the trigonal axis of the crystal Fig 2*a* shows the *c* plane projection of the crystal in S_1 Fig 2*b* shows the corresponding projection of its vector map in S_2, in which there are points the intensities of which are $2s^2$, s^2 and $2s^2 - 2os$

The S_2 projection shows that the molecules in S_1 are trigonal and that the molecular and crystal hexagonal axes are not coincident but make an angle with one another (say 6° in the figure) The dimensions of the molecule are obtained when it is realized that the distribution around the cell corners in S_2 implies a distribution around the cell corners in S_1 of half the dimensions The relative intensities of the points A B (s^2 and $2s^2$ respectively) make it possible to interpret the intensities on an absolute scale Finally, the lower intensity of the point C which contains a term $2s^2$, demonstrates the presence of an intensity at the centre of the molecule the sign of which is opposite to that of s, which, contributing, with the s points, a negative intensity $-2os$ to C, reduces the total intensity there to $2s^2 - 2os$



(a) (b)

Fig 1



(a) (b)

Fig 2

The illustrations given above have been selected, not only because they indicate the essentials of the geometrical method of approach to the problem of interpreting vector maps, but also because they are directly relevant to the case of insulin Thus, in Fig 2b the positions of the maxima A, B, C found in the c plane projection of the vector map of an insulin crystal calculated from X ray photographs are reproduced[9] The points associated with the hexagons obtained from the C_2 cages are also shown The superposability of these two sets of points represented the first stage in the proof of the correctness *of the C_2 structure proposed for insulin*[6] Fig 2*a* indicates the size and orientation of the molecules in the insulin lattice, deduced from the vector diagram, Fig 2*b*

Again, Figs 1*a* and *b* show how it proved possible[7] to deduce from the vector section, $z = \frac{1}{6}$[10] the presence and position of three 'foreign' high intensity points per molecule in the lattice, nothing whatever being assumed about the chemical composition of the crystal The images in Fig 1*b* around the cell corners and around the middle point of the cell of the original distribution around the corners of the cell in Fig 1*a* show how the existence and size of the negative intensity region at the centre of the insulin molecule was also deduced from this section[7] These investigations showing that it is possible to deduce that the insulin molecule is a polyhedral cage structure of the shape and size predicted, give some indication of the powerful weapon which the geometrical method puts at our disposal

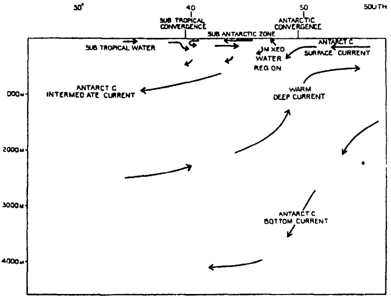
Marine Research in the Antarctic

THE wide scope of the investigations undertaken by the Discovery Committee in the Antarctic is well shown by the contents of their most recent reports[1] First comes an account of the hydrology of the Southern Ocean by G E R Deacon which includes two results fundamental to an understanding of world water movements

Of recent years the origin of the ubiquitous Antarctic bottom water, which in the Atlantic reaches as far as 40° N has stimulated oceanographers



VERTICAL CIRCULATION OF WATER IN THE SOUTH ATLANTIC OCEAN FROM DISCOVERY REPORTS VOL 15

As a result of the 1932–33 circumpolar cruise of *Discovery II*, we can no longer suppose that this bottom water is formed by the sinking of shelf water all round the Antarctic Continent Deacon now believes it to arise in, and only in, the south western and western parts of the Weddell Sea While moving eastwards, it incorporates water from the warm deep layer—now shown to exist throughout the whole of the Antarctic Zone—and the resultant highly saline bottom water flows northwards in the Atlantic Indian and Pacific Oceans It is the heaviest water in the sea

On all sides of the Pole Antarctic surface water also spreads northwards in a shallow surface layer until it reaches the Antarctic convergence There it plunges abruptly to a deeper level to continue its course as the Antarctic intermediate current The sharpness and constancy of position of the convergence is now shown to be governed by the movements of the warm deep water and the Antarctic bottom water The northward movement of the latter depends on the configuration of the bottom The sections at the end of the report suggest that near the convergence the bottom water is flowing steeply down hill to the ocean abyss As to whether this is always so the text is not very clear At any rate where the southward moving deep water is opposed by a large volume of Antarctic bottom water the former is forced up from below 2 000 metres to within 200 metres of the surface Over this ascending warm deep water the northward moving Antarctic surface water flows like a cascade to become the Antarctic intermediate current Room is then left above for the warmer and lighter sub Antarctic surface water This picture appears to apply not only to the South Atlantic but also to the Indian and South Pacific Oceans as well

There follows an account by A W B Powell on marine mollusca from New Zealand waters, describing six new genera, 128 new species and thirteen genera previously unknown there

Of the problems in the Antarctic requiring scientific study, perhaps the most urgent is the effect on the stock of Blue whales of modern intensive whaling methods. A H Laurie finds that Blue whales reach physical maturity at ten or eleven years of age and that they breed only once in two years at most and often only every third year The length of female Blue whales has decreased so much that on an average they are caught before they have had time to reproduce at all Continued fishing on the present scale must have a disastrous effect on the stock As Laurie points out, when killing has reached the point at which recruitment shall virtually have ceased, the future of Blue whales and whaling will be limited to the lifetime of those whales now living Shall it be said of whaling as may now be said of other branches of the fishing industry *inopem me copia fecit ?*

Progress in Building Research

A MATTER of considerable importance dealt with in the report for the year 1937 of the Building Research Board, by Dr R E Stradling director, is the account of the work done in connexion with "Soil Mechanics This is a new and rapidly developing branch of engineering science which, it is felt, has not received from practising engineers in Great Britain the measure of recognition accorded to it elsewhere The report therefore lays especial stress on the importance of recent developments in this direction In the past, it is pointed out, such civil engineering problems as those associated with foundations and the stability of cuttings and embankments, have had to be dealt with on an empirical basis As the necessary scientific knowledge did not exist this was inevitable , but a new school of thought has arisen and, following the lines explored by Terzaghi and others, the Station has been engaged in a programme of research In this it has been actively assisted by the Earth Pressures Committee of the British Association, and by an Earth Pressures Sub Committee set up by the Institution of Civil Engineers Abroad, the results of research have had a large measure of application and there are reported to be signs of increasing attention here, the inquiries received at the Building Research Station being taken to show that engineers are becoming more fully aware of the assistance which this new science can give in promoting accurate and economical design This increased interest has had the result that the soil mechanics section at the Station has been strengthened and it is hoped, with the support of outside bodies interested in its aims, to extend its operations and so to hasten the work of fundamental research and the solution of problems of immediate practical interest

The two avenues of soil research which have been mainly followed at the Station are in connexion with the settlement of structures and the stability of earth slopes In its method of dealing with the former the development of this science has led to a complete change in the mode of approach to this type of problem In the past, it was held that the type of soil alone governed the pressure which could be imposed upon it From the accumulation of practical experience, certain broad rules were evolved and, as a result, the so called 'bearing values' of different soil types were embodied in tables which formed the basis of design In difficult or doubtful cases loading tests might be carried out, usually on comparatively small areas, in an endeavour to assess the bearing value in these cases

The new mode of approach is through an understanding of the mechanism by which settlements take place and, considering the structure itself, the relative amount of settlement permissible as between one part of the structure and another is regarded as the determining factor in the design of the foundations It is to the work of Terzaghi and his followers that an appreciation of the broad aspects of the problem is due Although, as the report states, the mechanism by which settlements occur has not as yet been fully explained, it is understood that settlement depends not only on the type of soil immediately below the footings but also on the nature of the soil strata to a considerable depth A deep seated stratum of soft clay may be, and indeed has often been, the cause of serious settlement Apart from the influence of the pressure on a footing, settlement depends on the *size of the footing the depth at which it is placed* and the presence of other footings in the immediate proximity In the case of clay soils, time is also an important element, for settlement continues at a diminishing rate for a period determined by the conditions, and failure may occur some time after the completion of the structure With so many factors entering into the problem, the difficulty in interpreting the results of loading tests and in appraising the limitations associated with them becomes obvious

In the second part of the report, which contains the more detailed account of the Station's activities during the year, an outline is given of the methods employed in estimating and analysing the settlement of a structure It is based on the laboratory examination of soil samples taken in an undisturbed' condition from several strata beneath the structure From the results of tests made with the Terzaghi oedometer together with calculation of the distribution of pressure from the building, it is possible to estimate the amount of settlement to be expected It may be objected that the conditions of the test do not actually reproduce those existing in practice, and this is acknowledged, but if, from actual measurements, agreement can be shown between the actual and the estimated movements, then a very great step forward can be recorded This represents the present stage of development of the subject , every effort is being made to get information about such comparisons and, the more the work progresses, the more impressive does the closeness of the correlation appear The results of work done in connexion with a new building for the Fire Testing Station, Elstree, will shortly be published and it is claimed that the agreement in this case is as near as one can hope to get. Further cases are under observation and, as the data from these become available, this method of testing and analysis will be more firmly established It certainly provides a much more accurate design technique than any other known method

On the cognate subject of the stability of earth slopes, the report states that special opportunities have arisen during the year for the study of earth bank failures on a practical scale, and the various engineers concerned have given facilities for samples and measurements to be taken on the sites It is now held that the stability of an earth slope depends upon the shear characteristics of the soil in the slope and in the foundation layers The shear resistance of clay has been shown to depend on its cohesion, with the result that the maximum angle at which a clay slope can stand without support decreases rapidly with increasing height This puts a new complexion on the problem, and the report shows how progress is being made to determine the properties of soils and how these and other aspects of it are being investigated

These notes treat of but one of the many interests being dealt with by the Station, ranging from the homely problem of the smoky chimney through the whole gamut of building problems to research on the constitution and properties of materials Both in its routine work and in special investigations the fact is clearly recognizable that the services of the Station are of great value to the building trade and to the nation, as well as to the promotion and development of applied science in a wide field

Australian Echinoderms

DR H L CLARK'S first papers on Australian echinoderms appeared in 1909 when he described the Australian forms in the Museum of Comparative Zoology, and the *Thetis* collection made off New South Wales and at Lord Howe Island They proved to be the forerunners of a series, continued to the present day*, in which he has made known far more about Australian echinoderms than any other man He has described the collection of the Western Australian Museum (1914), the many echinoderms, excepting the holothurians, taken by the *Endeavour* off the coasts of Queensland, New South Wales, Tasmania, Victoria, South and Western Australia (1916), a small collection from Western Australia (1923) and another from the Barrier Reef (1926), the very large collection, other than the holothurians, of the South Australian Museum (1928), mostly southern forms, and the echinoderms, other than asteroids, of the Barrier Reef Expedition (1932)

All but the first of these papers were on collections submitted to Dr Clark, as an expert in another country, by Australian and other authorities The collections comprised nearly 6,000 specimens among which were representatives of 113 new species In the meantime, in 1913, Dr Clark had been to Australia himself and had made a large collection in the Torres Strait It was described in two papers in 1915 and 1921

These notes on earlier papers are given as a background against which to see Dr Clark's most recent work They show that he had described a great deal of material from all coasts of Australia except the north western, which remained a *terra incognita* in marine zoology His most recent paper describes the very rich echinoderm fauna he found in the north west and much additional material from all other coasts as well

It is based on specimens which for the most part he himself collected, alongshore and by dredging, on his visits to Australia in 1929 and 1932 Treating the two visits as one, he spent six weeks at Darwin, visited two points on the coast between Darwin and Broome and spent three months at Broome, small collections were made, where echinoderms occurred, at five points between Broome and Perth, and three weeks collecting was done from Fremantle There followed short visits to study the material at the Museums of Adelaide, Melbourne, Hobart, Sydney and Brisbane and collecting excursions from some of them Finally, three weeks were spent at Lord Howe Island in the Tasman Sea

Dr Clark returned to America with more than 11,000 specimens of echinoderms of which he and his immediate helpers, including Mrs Clark, collected nearly 10,000, the remainder being loans and gifts from museums and other sources in Australia They represented 422 species of which 128 were new The descriptions of the species are as in Dr Clark's papers on the Torres Straits collections, richer because the author saw them alive and observed their abundance and habits and colours His descriptions of these things will be invaluable to those who may seek the animals in life They are of great interest to students who cannot, for them Dr Clark has described too the colours the species have when dried or kept in spirit—though it is often the dingy brown called museum colour There are eighteen beautiful coloured plates based on sketches made from life by Mrs Clark, they and the coloured plates of the Torres Straits report must make the Australian echinoderm fauna one of the best illustrated in colour in the world

The report falls into five sections corresponding to the five echinoderm classes Before each, Dr Clark tells us, among other things where the members of this class are most abundant in Australian waters, in what sites they should be sought and how they may best be fixed and preserved Because the species of the starfish genus *Anthenea* are mostly Australian and Dr Clark had a large series before him, he has discussed or described all the known species and given a key to them In the ophiuroid section he has made a beginning with—what has long been overdue—a sub division of the large genus *Ophiothrix* starting with the long armed species of the Indo Pacific region At the end of the volume are local lists of echinoderms for ten localities

Dr Clark has in earlier papers discussed the geographical distribution of the Australian echinoderm fauna and its relationships to that of other regions Now that he has collected and described so much new material, a great deal of it from the hitherto unknown north west, it is good to know that in a subsequent report he hopes to give a full account of the fauna as at present known, and to discuss its apparent history and relationships D D J

Science News a Century Ago

Engineering Education

THE *Athenæum* on September 29, 1838, in a review of some recently printed pamphlets, gave its views on engineering education At the head of the review it mentioned the "Program des Cours de l'Ecole Centrale des Arts et Manufactures", regulations for students in civil engineering in the University of Durham, arrangements for conducting the various departments of King's College, and the prospectus of the class of civil engineering and mining, University College, London In the course of the review, the *Athenæum* remarked But no man pursues his trade or art successfully or well, who does not, beside the practice, possess the science of it, and the great distinction between artificers, for the most part practically equal, is this, that some have and some have not the knowledge of the science of their art Science is everywhere aiding man in his contest with the physical difficulties of his position, and ministering to him new powers and capabilities of thought and action "

Treatment of Wounds by Heat

"THE rapid cicatrization of wounds by heat has been the object of several experiments made by Drs Breschet and Jules Guyot To severe wounds and amputations they apply a heat of 36° of the centigrade thermometer The apparatus consisted of a box, carefully constructed, in which is a glass, through which the progress of the wound may be watched, and communicating with a tin tube, adapted to a lamp, precautions are taken to prevent the contact of the wound with the wood of the box, and a piece of linen or other material surrounds the orifice, and ties above the wound, when once adjusted, the apparatus is left on without any other application till the wound is healed M Larrey has remarked on this, that the heat of Egypt seemed to him to be highly favourable to the cure of wounds, inasmuch as they were healed in half the ordinary time, but he doubts whether the application of local and artificial heat will have the same effect as that of atmospheric air ' (*Athenæum*, September 29, 1838)

Whitby and Pickering Railway

IN its early days, the Whitby and Pickering Railway, opened in 1836, was worked by horses, the carriages consisting of stage coaches with flanged wheels It had heavy gradients and at one of these a tank was provided, mounted on railway wheels, at the top of the incline To assist in drawing a coach up the incline, the tank was allowed to descend the reverse slope and at the bottom the tank would be emptied Airy, the Astronomer Royal, who was visiting Yorkshire at the time, wrote from Brampton, near Chesterfield, on September 30 "On Wednesday morning at 8 we started by the railroad (from Pickering) for Whitby in a huge carriage denominated the Lady Hilda capable of containing 40 persons or more drawn by one horse, or in the steep parts of the railway by two horses The road goes through a set of defiles descending in one part by a long crooked inclined plane, the carriage drawing up another load by its weight . The rate of travelling was about 10 miles an hour Betsy declares that it was the most agreeable travelling that she ever had "

The Changing Outlook for Engineering Science

WHAT policy should govern the content of university training in engineering science? What policy should govern research? What policy should govern relations with the community? These were the three main questions dealt with by Prof. R. V. Southwell in his presidential address delivered at Cambridge to Section G (Engineering) of the British Association. No one, we believe, would disagree with Prof. Southwell that the time for a general stocktaking, such as is implied by the questions, has arrived.

> "It is a commonplace," he said, "that the boundaries of natural science have so extended that no man can hope to comprehend the whole of physics or chemistry or any other field. But engineering science embraces all these fields; its boundaries extend not only continuously, as knowledge grows in tracts already surveyed, but at times by a sudden accretion of new territory—as when recently the new technology of plastics came to replace, for many purposes, older methods of fabrication in wood and metal . . . What is to be our policy in the face of this continuous accretion of knowledge, seeing there is no corresponding increase in the capacity of undergraduates to absorb?"

It will be generally agreed that mere lengthening or intensification of academic courses will not solve the problem, and that the planning of time-tables, in Prof. Southwell's words, "must be conditioned first and foremost by ineluctable limits to the instruction we can give with confidence that it will really be assimilated". No intensification or lengthening of courses can guarantee the production of men of personality, educated to take wide views, which Prof. Southwell tells us are what industrialists demand. The filling of every hour of the working day by lecture or laboratory courses, which leave little or no time for "undergraduate activities", may well cut out just that part of a university training most likely to develop the very qualities that should be produced.

Clearly, in shaping courses, the purpose which they are to serve must be decided, and here Prof. Southwell's view is clear: "their purpose is to train recruits for industry, and the taking of honours in a final examination should indicate an assimilation of engineering principles adequate in a man who is starting a professional or industrial career—*but not more than this*". With that end in mind he sees that "the real and difficult duty of a professor is to decide, not what subjects of instruction should be included because of value, but what can be omitted on the ground that, pushed into a mind already taxed, it will push out something still more valuable".

But how decide what can be omitted? Prof. Southwell would call industrialists into council; and in this connexion he puts his finger on a vital spot. Very rightly, he insists that the time is past when a student's three years at the university and his two years' apprenticeship can be regarded as distinct phases in training. The five years should be an integrated whole devoted to a single objective. He would therefore, with the industrialists, work out a plan to secure the recruits which are wanted. He would not neglect the importance of leisure in the formation of personality, and he would ask that industrialists scrutinize syllabuses, so that they may say whether items can be omitted either as never likely to be applied in practice or as being easily and more appropriately learned in works.

He displays a proper educational care He would not engage to drop a subject simply because an industrialist has not found it useful—that may be an accident of particular interests—but he would examine suggestions and find out, perhaps, "much that has crept into our courses more by accident than design"

There will be general agreement with all this but there are difficulties which must not be overlooked Who are the industrialists to be called in ? Is there a body of industrialists who can be asked to do what is required ? The idea has been used, of course, in certain technical colleges : but when the need is for the re-shaping of university syllabuses, something more is required of the details of how industrialists are to be secured who can and will help in this work

With Prof Southwell's views on research we are in entire agreement He has given the answer to the pessimistic view that engineering research at universities is doomed because, as it makes even fuller use of mathematics and physics and chemistry, its problems will be such as must more and more be referred to specialists in those subjects, and because of the vastly increased provision for *ad hoc* experimentation which has been made since the Great War in Government departments and in industrial concerns As he points out, the engineer's problems are inexorable and he must so recognize them The physicist, for example, is free to choose his "shapes" they "are not dictated by constructional or manufacturing requirements, nor his materials by considerations of strength and cost" There are still countless problems of engineering, too difficult for routine investigation, which will provide vast scope for academic engineers

When Prof. Southwell comes to the question of engineering as it concerns the life of the community, he reminds us that, because man has not learned to use his mastery of Nature wisely, he now often questions its value "Because engineering includes guns, battleships, aeroplanes, tanks, therefore engineers are regarded as a class more than others responsible for the horrors of modern war." So runs the argument (with variations, of course ; sometimes it is the chemist or some other specialist, but practically always it is "the scientist") we hear so often in these days of international trouble and crises. Prof. Southwell answers that the engineer is as much responsible as any man, *but no more* We ought to be grateful for his succinct summing up of the matter when he says. "When men talk of 'beneficent' and 'destructive' science as though we were free to pick and choose, then I say they have not even begun to understand what science is " Obviously, we cannot have the benefits of science without its risks and temptations

When the impact of science on life produces grave problems, hard and clear thinking is required ; but here Prof Southwell's view is that "we only confuse the issue when we intervene *as specialists* in discussions which concern us really not as specialists, but as members of a community" He thinks, therefore, that the scientific worker must come to political discussions unlabelled, in hours of leisure rather than give support to a notion that political problems will yield to something known as "the scientific attack" "Talk to me of the scientific approach in physics and I shall have some idea what you mean talk to me of a 'scientific approach' to problems of real life, I shall suspect you of indulgence in mere jargon " He goes on to say that, instead of defending himself against the charges of dreadful responsibility for horrors, the man of science should devote himself to instilling into the public mind a clearer notion of the aims with which real scientific work is done The popular notion of the "wonders of science" performed by workers aloof and remote from the world might be cleared up by giving a picture of these people doing their jobs and "seeking truth like artists because they must"—a picture not of the treasure found, but of the quest in search of it.

Such popular misconceptions must certainly be cleared up , but that is not enough It may be argued that the search for abstract truth is not sufficient Truth is relative, and the search for it must have some relation to the life of the community. For that reason a "scientific approach to problems of real life" cannot be regarded as mere jargon · and while it is not necessary to believe that a specialist in a particular subject will necessarily think clearly on matters of ethics and politics, nevertheless a scientific approach to modern problems can be formulated with enormous benefit to the modern world.

Prof Southwell is to be congratulated on his stocktaking—the more so because he urges the obvious need for planning as the outlook for engineering science changes, and because, if that planning is to be done efficiently, we must strive to find agreement on problems which will not lightly tax both courage and skill.

A Pioneer of Long-Distance Telephony

The Collected Papers of George Ashley Campbell, Research Engineer of the American Telephone and Telegraph Company
Pp xii + 581 + 1 plate (New York and London American Telephone and Telegraph Company 1937) n p

DR G A Campbell who has recently retired from active service with the American Telephone and Telegraph Company is well known to telephone engineers for his many contributions to the theory and practice of telephony One of his best known inventions is the wave filter which bears his name by means of which the harmonics in the electromotive waves produced by a generator are effectively suppressed by means of a multiple system of condensers and inductances To commemorate his retirement the American Telephone and Telegraph Company has issued this handsome volume of his collected papers The representative of this company in Great Britain has written stating that requests for copies of the book will be entertained so long as the somewhat limited number of volumes printed lasts Requests should be addressed to Dr L F Morehouse American Telephone and Telegraph Company Bush House London W C 2

A few years after the invention of the telephone by Bell the present plan of organizing the Bell System had been evolved The unusual requirements of the telephone industry were met by an organization having licensee telephone units and a manufacturing unit grouped around a parent company In 1897 the American Bell Company the functions of which as the parent company were taken over later by the American Telegraph and Telephone Company had by gradual steps built up a research organization of physicists chemists and engineers It was then located in Boston under the direction of Dr Hammond V Hayes In 1937 this department appears a small group but so late as 1897 organized industrial research was scarcely known outside the Bell System In those days the Bell System had 325 000 stations compare this with the 14 million stations of to day

Forty years ago long distance telephony had begun to come to the front but line costs were high and a practically commercial range did not exceed a thousand miles Hence the two main objectives were to secure better and more economical circuits and to explore the possibilities of reaching greater distances The rapidly expanding telephone business about large cities soon made it necessary to place telephone circuits in cables The study of these circuits presented many problems to the engineer and called for considerable mathematical knowledge Dr Hayes was faced with the problem of adding to his staff one who had a good working knowledge of advanced electrical theory—work recently developed by Kelvin Maxwell Weber Heaviside and others of the great mathematical physicists of the nineteenth century He appointed Dr George A Campbell a graduate of the Massachusetts Institute of Technology who had also had five years study at Harvard Paris Vienna and Gottingen This appointment was fortunate and timely for the communication industry

In an introductory chapter Mr Colpitts says that soon after Campbell's appointment he was engaged in developing cable circuits At the same time and independently Prof M I Pupin was engaged on the same problem and his patent slightly anticipated Campbell's The Associated Companies immediately acquired Pupin's patents Campbell's analysis was more thorough and led him to formulæ more convenient than his rival's The latter alone were employed for the building of loaded lines in the United States When engaged in this work he invented his famous wave filter

It was found that all the questions relative to loading coil design depended on the quality of the iron used in the core The best results were obtained using iron of normal permeability and very high resistivity In 1900 a successful experiment was carried out between Bedford N Y and Brushton Pa a distance of 670 miles over a loaded cable Campbell was the inventor of the single transformer anti sidetone circuit which is now almost universally used

Perhaps Campbell's best known paper is that On Loaded Lines in Telephonic Transmission published in the *Phil Mag* in 1903 Even at that early date he had begun to consider the problem of the high pass and the low pass wave filters As an early investigator of antenna arrays to secure directional transmission Campbell did excellent work and holds certain fundamental patents in this field He is at present taking a leading part in the struggle to get the adoption of a rational system of physical units

Although the volume extends to nearly 550 pages, all Campbell's researches are not included in it We hope that he will continue his researches for a long time to come

A R

Aspects of Nuclear Physics

(1) The Newer Alchemy

based on the Henry Sidgwick Memorial Lecture delivered at Newnham College Cambridge November 1936 By Lord Rutherford Pp viii + 68 + 13 plates (Cambridge At the University Press 1937) 3*s* 6*d* net

(2) Elements of Nuclear Physics

By Prof Franco Rasetti Pp xiv + 327 (London Glasgow and Bombay Blackie and Son Ltd 1937) 18*s* 6*d* net

(3) Die Atomkerne

Grundlagen und Anwendungen ihrer Theorie (Physik und Chemie und ihre Anwendungen in Einzeldarstellungen Band 2 Von Dr C F von Weizsäcker Pp viii +214 (Leipzig Akademische Verlagsgesellschaft m b H 1937) 16 gold marks

(4) Einführung in die Kernphysik

Von Dr H Kallmann Pp vi + 216 (Leipzig und Wien Franz Deuticke 1938) 12 gold marks

(5) An Outline of Atomic Physics

By members of the Physics Staff of the University of Pittsburg Second edition Pp ix + 414 (New York J Wiley and Sons Inc London Chapman and Hall Ltd 1937) 18*s* 6*d* net

A COMPARISON of Dr Gamow s well known book Constitution of Atomic Nuclei published in 1931 with say Dr von Weizsacker s book in the list above almost persuades one that they deal with different subjects The discovery of the neutron and of the positive electron the disintegration of elements by accelerated protons and deuterons and the discovery of artificial radio elements have all taken place since the publication of Dr Gamow s book In 1931 only a few examples of nuclear processes were known those of the natural radioactive elements at one end of the periodic table and those cases of artificial disintegration produced by α particles amongst the lighter elements At the present time some hundreds of nuclear reactions have been reported and new series of transformations have been caused by neutron bombardment to start in uranium and thorium

The rapid developments which took place in these few years led to many changes in outlook and to a wide extension of the field of inquiry When this exciting period was followed by comparative calm it was natural that many writers should seize the opportunity to assimilate the new knowledge and to give a connected account of nuclear physics in a form suitable for students and for research workers It will be immediately obvious to readers of these books that much of our knowledge in nuclear physics is still unsatisfactory and our understanding vague and incomplete The subject could not remain long in the state depicted here Nor has it The discovery of a new particle the Yukawa particle or heavy electron has given a new orientation to many of our ideas This may indeed prove to be a most significant advance towards a satisfactory theory of nuclear problems but its full bearing has yet to be appreciated and worked out In the meantime however the books reviewed here give in their different ways excellent surveys of the subject

(1) The late Lord Rutherford s lecture gives a refreshing account of the development of nuclear physics Small as is its compass it contains the essence of the subject From a brief account of the natural radioactive transformations it leads to a discussion of the elementary particles of matter the experiments on artificial transformations by α particles and the discovery of the neutron and the production of radioactive bodies There follows a description of methods of producing high voltage ions for use in artificial transmutations and an account of some simple cases of transmutation In its clarity and directness and above all in its stimulating enthusiasm and vitality this book is characteristic of its author All interested in physics should enjoy it

(2) This book contains exactly what its title implies—a survey of the facts and theories on which nuclear physics is based Prof Rasetti gives a general account of radioactivity the properties of the radiations and their interaction with matter He then discusses the properties of atomic nuclei and the theory of nuclear structure leading to a description of the artificial transmutations The book concludes with a short chapter on cosmic rays

The important facts are brought out clearly and so far as possible explained in general terms In certain cases for example internal conversion of γ rays the α decay the general problem of collisions a more detailed theoretical analysis is given Throughout the treatment is clear concise and easy to follow Many illustrations and tables are given and the printing is good This is an excellent introduction to the subject and it can be strongly recommended

(3) Dr von Weizsäcker assumes a knowledge of the experimental facts and builds upon them the general theory of nuclear physics so far as it

has been developed and generally accepted His book will appeal both to the experimental worker who wishes to know how far his results can be explained and to the theoretical worker who inquires what particular problems require further examination and in what respects the present explanations are unsatisfactory

As a rule important questions are first discussed from a general physical point of view and then the mathematical theory is developed in detail This procedure is especially useful to the experimental worker The subjects dealt with are the foundations of nuclear theory the structure of the nucleus natural and artificial transmutations and the problem of the β disintegration The treatment is extremely thorough and complete There are many diagrams and tables and the printing is good This is a valuable book for those specially interested in nuclear physics

(4) In many respects Dr Kallmann s book is intermediate between those of Prof Rasetti and Dr von Weizsacker It is broadly speaking an account of the present state of the subject in which the object seems to be not so much to build up a general theory of nuclear physics but rather to describe the experimental results in terms of fairly simple concepts The formulæ of quantum mechanics are usually quoted and not established This is not to say that the description is qualitative rather than quantitative The book is clearly written and the arguments are easy to follow It will fill a useful place in the literature of the subject It should perhaps be mentioned that the date on the title page is 1938 although the book appeared in 1937

(5) This is the second edition of a most useful and interesting book for the general student of physics It deals mainly with atomic structure and the nature of radiation but two chapters are given to radioactivity and nuclear structure The theory of relativity is discussed and there is a long and interesting chapter on astrophysics For a general text book on atomic physics the scope is very wide

It is inevitable that some minor inaccuracies and loose statements should occur Thus we read on p 44 in the nuclei of the heavier atoms electrons and protons are closely packed together On p 260 the mass of the proton is given as 1 00815 this is the mass of the hydrogen atom The illustrations and diagrams are on the whole very good but here again are some which are not up to the high standard of the book For example the reproductions on p 230 might be better the photograph of p 258 is not what the legend says it is These however are small defects in what is an admirable and stimulating book for the inquiring student

Reproductive Rhythm in Man

Season of Birth

its Relation to Human Abilities By Dr Ellsworth Huntington Pp viii + 473 (New York John Wiley and Sons Inc London Chapman and Hall Ltd 1938) 17*s* 6*d* net

THIS volume is designed to throw light on some of the interesting problems connected with the seasonal variations in the birth rate The author has managed to collect a great deal of material on the month of birth in different parts of the world It seems that accurate information on the month of birth is not too easy to obtain In Italy it is common practice to postpone the registration of those born in November and December until January since this delays military service for a whole year In pre War Russia many births which took place in December were not registered until the following January owing to the fact that the central Government insisted that end of year reports should be sent in even though they were incomplete This end of year error is common to a great deal of data on the month of birth

The author s main thesis is that man has acquired an innate reproductive rhythm which is set in motion by the weather and such related conditions as sunlight and diet and which is so adjusted that the young are born at the season when their chances of survival are greatest A little later in the book after a discussion of the seasonal distribution of births he concludes that the basic reproductive rhythm depends primarily on temperature factors such as diet being of secondary importance and that the optimum mean diurnal atmospheric temperature for conception to take place is 62° F The author maintains that the chief advantage of an infant being born in the late winter or early spring lies in the fact that at that time there will be an increasing supply of milk for the following months and that the infant will have developed sufficient control of body temperature before the onset of the heat of summer

The effects of fasts, feasts and religious ceremonies seem to have a considerable influence on the incidence of conceptions, especially among highly superstitious peoples such as existed in pre-War Russia Unfortunately, no post-Revolution figures are available for comparative purposes A great deal more information is needed on the season of marriage, and the month after marriage when the first child is born, together with the economic circumstances underlying such seasonal variations as do occur, before the hypotheses in this book can be established

The discussion of the season of birth of abnormal types such as psychotics and mental defectives is intermingled with much unusual and unconventional theory We read on p 396 that "the most important cause of mental deficiency is environmental conditions which act upon the child during pregnancy, at birth, and onward throughout life" There may, of course, be some truth in this statement, but if it is untrue, then this section of the work is largely invalidated

As the book proceeds, more weight is placed on the effect of atmospheric temperature on the seasonal distribution of births and less on other factors such as diet On p 417 we read that "Temperature appears to be the main factor" Most of the work done on the relationship between diet and fertility has been entirely neglected There may possibly be some powerful and direct relationship between atmospheric temperature and fertility, but on the other hand there may not

It is always a difficult task to make a critical estimate of the value of a book of this size The author tells us that the work has taken two years, but in view of the immensity of the problems studied, which are biological, psychological and sociological, it would be unfair to expect more than a general survey of the field and a set of likely hypotheses worthy of investigation The spirit of enthusiasm which pervades this work should do much towards stimulating further research into this interesting and unexplored field

Study of the Bantu

Bantu Beliefs and Magic:

with particular reference to the Kikuyu and Kamba Tribes of Kenya Colony, together with some Reflections on East Africa after the War. By C W Hobley Pp iii + 368 + 11 plates (London H F and G Witherby, Ltd, 1938) 15s net

Mr HOBLEY'S study of Bantu beliefs and magic, dealing more specifically with the Kikuyu and Kamba peoples of Kenya, was first published in 1922. It was at once recognized as work of the first order, both as a study of these African peoples, and as a contribution to the general stock of anthropological material, most notably perhaps in its observation and interpretation of the place of the concept of *thahu*, the 'curse', as an element in their life and thought The importance of this concept was duly stressed by Sir James Frazer in his preface to the original edition. The book has long been out of print. A new edition is welcome, not only because it makes accessible once more a book essential for the student, but also because much water has passed under the bridge since its original appearance Mr. Hobley can now compare present-day conditions with his diagnosis of the native situation in the immediate post-War years.

The comparison redounds to the credit of Mr. Hobley's understanding of the people and the sanity of his judgment He is no doctrinaire, he gauges the needs of the moment with the eye of an administrator Although it is now many years since he retired, he has kept closely in touch with the trend of events, while his detachment from controversial strife is obvious

Mr Hobley shows a ready appreciation of the value of the work of the native councils, but in his view the crux of future development is education, with finance as a stumbling block Missionary education, though economical, is deprecated as for the most part in the hands of those who are untrained. At the same time he does not agree with the views of Lord De La Warr's Commission on the necessity for developing a system of higher education Mr Hobley would rather see efforts concentrate on secondary education. He holds that the young African is not so intelligent as the average European, though malnutrition may be in part responsible. The best solution of Africa's problem he can find is co-operation. It may be that his wisest advice is "Trust the settler", but by 'Young Africa' he is not as yet greatly impressed

However much any reader may disagree with Mr Hobley on specific points, he will have to admit that, as a whole, his survey is judicial in its attitude and in its outlook sane

La notion de temps

temps physique et relativité, la dynamique du point matériel Par Ernest Esclangon Pp iv + 77 (Paris Gauthier Villars, 1938) 20 francs

THERE is nothing very new in this little essay by the Director of the Paris Observatory, but it is a lucidly written contribution to that subject which is now almost universally known as the philosophy of science M Esclangon introduces his discussion by a consideration of metaphysical time which he decides can be reduced to a sensation that is individual in every one of us and owes its existence to a kind of biological clock to which we refer our sensory perceptions The extension of this idea to a Being who although infinite and therefore beyond our powers of conception yet dominates the universe and is equipped with a form of consciousness akin to our own, has given birth to the illusion of a real and absolutely independent time This illusion has only been dispelled—with considerable difficulty —from human minds by the concept of relativity M Esclangon concludes that apart from the various times defined by a series of conventions which are the creation of science and form the subject of discussion of the rest of the book there is only this subjective, individual time of which the true nature must for ever remain mysterious and impenetrable

For the rest M Esclangon discusses these various scientific times—of which one example is the time of the special theory of relativity—examines the principle of reciprocity with a description of Fizeau s experiment the invariance of natural laws in uniform translation and the equations of dynamics which are deduced from the principle of reciprocity He does not minimize the difficulties involved in all physical theory, and is of the opinion that at present no firm territory is to be found in those regions which lie at the frontiers of present day science A V Z

Bird Flocks and the Breeding Cycle

a Contribution to the Study of Avian Sociality By Dr F Fraser Darling Pp x + 124 + 1 plate (Cambridge At the University Press, 1938) 6s net

THE author spent about two years on uninhabited Priest Island, off the north west coast of Scotland There he observed the breeding behaviour of the sea birds, particularly of the lesser black backed and herring gulls He reports on his observations in this book, and presents a shrewd conclusion which one feels may lead to the solution of many problems, such as the lack of elasticity or recuperative power in the population of a species when its numbers fall below a certain level It is understood by the majority of naturalists that the breeding behaviour of individual pairs is a sufficient stimulus to bring mating to its successful conclusion Now Dr Darling finds in certain birds which have social habits that the proper pitch of emotion can only be reached by the combined behaviour of a certain minimum population

This is an important contribution to the study of animal behaviour, and a book which brings to the layman from the authority himself the result of his scientific observation J D M

The Hypothalamus

Morphological, Functional Clinical and Surgical Aspects By Dr W Le Gros Clark Dr John Beattie Dr George Riddoch and Norman M Dott (The Henderson Trust Lectures, Nos 13 16) Pp xii + 212 (Edinburgh and London Oliver and Boyd 1938) 12s 6d net

THE importance of the region of the brain near the pituitary gland has been recognized with increasing clearness in recent years and a review of modern knowledge of the hypothalamus is therefore welcome The book consists of an amplification of the Henderson Trust Lectures which were delivered in Edinburgh in October 1936 by the four authors Prof Le Gros Clark s section gives a detailed account of the development and anatomy of the hypothalamus in mammals with a special section on man and smaller sections on reptiles amphibians and fishes Dr Beattie discusses the physiological evidence which has led to the conclusions that the hypothalamus controls sleep the pituitary and the reactions of the body to heat and cold and that the anterior portion controls the parasympathetic system and the posterior portion the sympathetic system Dr George Riddoch discusses the pathology of the region and Mr Norman Dott describes four cases in which he removed tumours Both of them independently describe the clinical symptoms and signs associated with hypothalamic disease—the hunger and the thirst, the obesity and the cachexia and the disturbances of sleep, sex temperature and the stomach

The book is attractively produced with more than a hundred figures and diagrams and an adequate bibliography

About Petroleum

By J G Crowther Pp xiv + 181 (London Oxford University Press 1938) 7s 6d net

THERE are a great many people who use petroleum in some form or other every day of their lives without really knowing anything about it Some of them from time to time are actuated by the desire to find out what it is and where it comes from Unfortunately however petroleum is such a complicated substance both chemically and physically that the normal run of text books is comprehensible only to those who have specialized knowledge of the subject Mr J G Crowther in his book anticipates questions that must arise in the minds of motor drivers, business men housewives and others in the course of their daily duties, and endeavours to give simple answers to these The result is that within the confines of a slim volume information is given in a form palatable to the non scientific mind on all major aspects of petroleum technology The text is amplified by means of carefully selected photographs and easily interpreted diagrams Moreover there is an exhaustive index which facilitates easy reference to the vast number of facts which have been used as a basis of this work There is little doubt that the author s aim will be achieved and that this book will serve as an excellent primer to more comprehensive treatises on petroleum

German Forestry

By Prof Franz Heske Pp xxv + 342 + 16 plates (New Haven Yale University Press, London Oxford University Press, 1938) 14*s* net

THIS is a large book of 342 pages, and has been chiefly written for the American forester Dr Heske deals chiefly with forest economics and policy The character, extent and ownership of forests in Germany, the growth, production and utilization of wood materials and the general public services of the forests in the protection of watersheds, in the conservation of wild life, affording recreation and in maintaining industries, employment and stabilizing communities An interesting fact is stressed Until recently the management of the forests was under the different German States with a consequent difference in policy A greater measure of control of policy by the central Government is now being introduced, a factor which is all to the interests of the country as a whole

The new departure in such well established forestry countries as Germany and the former Austria would appear to merit close attention in India, where the devolutionary pendulum has swung so strongly in the contrary direction

A Bibliography of Eastern Asiatic Botany

By Elmer D Merrill and Egbert H Walker Pp xlii + 719 (Jamaica Plain Mass Arnold Arboretum of Harvard University 1938) 12 50 dollars

THIS magnificent volume, which in truth deserves the hackneyed adjective monumental, places all workers on the botany of the Far East in a deep debt of gratitude to the indefatigable authors The area covered comprises China, Japan, Formosa, Korea, Manchuria, Mongolia, Tibet, eastern and southern Siberia, and neighbouring regions The main body of the work consists of an alphabetical index of authors under whose names the references are arranged chronologically The scope of each reference is briefly summarized In addition there are separate general geographical and systematic indexes, and three appendixes on Oriental bibliography

The volume contains references up to and including 1936, and appears to be remarkably complete The authors and sponsors are to be congratulated on the production of a work which will greatly lighten the labour of future research in the flora of eastern Asia

The Dragonflies of the British Isles

By Cynthia Longfield (The Wayside and Woodland Series) Pp 220 + 260 illustrations (London and New York Frederick Warne and Co , Ltd , 1937) 7*s* 6*d* net

THIS handy manual should prove of material help in popularizing the study of British dragonflies It is the first to appear on the subject since Lucas's handbook of 1900, which is expensive and now out of print Miss Longfield has achieved a judicious blend of scientific accuracy with an absence of all except a very few technicalities, which is what is needed in a work of its kind It will serve as a guide to the identification of native British species and an introduction to their habits and distribution Methods of collecting and preserving specimens are described, while a scientific classification of these insects is appended at the end for those who need it It is up to date, fully illustrated and, in every way, a reliable little volume We hope that it will arouse more interest in these insects than prevails at present, for there is much spade work, such as their range of distribution in the British Isles, which the amateur might study to advantage

Mechanics, Molecular Physics, Heat and Sound

By Robert Andrews Millikan, Prof Duane Roller and Prof Earnest Charles Watson Pp xiv + 498 + 54 plates (Boston, New York Chicago and London Ginn and Co 1937) 4 dollars

THIS text book by American authors, seems to be nearly an ideal one for the intermediate science examination of British universities The style is excellent and it contains many beautiful plates illustrating the history of physics It is perhaps particularly valuable for the presentation of mechanics as a branch of physics with its mathematical side, although not shirked, put in its proper perspective , but the other sections are almost equally good A student who has used this book will not have to relearn what he already knows in any essentially new way on proceeding to more advanced work

Höhenstrahlung (Ultrastrahlung)

Von Dr Erwin Miehlnickel (Wissenschaftliche Forschungsberichte, Naturwissenschaftliche Reihe, herausgegeben von Dr Raphael Ed Liesegang Band 44) Pp xvi + 316 (Dresden und Leipzig Theodor Steinkopff 1938) 23 50 gold marks

STUDY of the cosmic radiation has entered on a new phase with the recognition of the probable existence of a heavy electron Dr Miehlnickel's account of the subject deals with the ground covered prior to this discovery It is written in the style of Meyer and Schweidler's handbook of radioactivity, and although primarily categorical is nevertheless full of interest For a book of this type the illustrations are good, but it would have been improved by more Wilson cloud pictures The most valuable feature of the book is the classified bibliography interspersed throughout the text

Bombyliidæ of Palestine

By E E Austen Pp ix + 188 + 4 plates (London British Museum (Natural History), 1937) 15*s*

THIS monograph is concerned with the rich fauna of Bombyliidæ found in the relatively small country of Palestine The bulk of the collection upon which it is based was formed by the author during the Palestine campaigns of 1917–18 in the Great War Out of 128 species or varieties dealt with in its pages no fewer than 46 are described as new The work is a model of its kind—admirably clear descriptions, first rate text figures and excellent printing It does credit to all concerned in its production

Ley-Farming and a Long-Term Agricultural Policy*

By Prof R G Stapledon, C B E

IN view of the immense amount that has been published during the present century it is not without significance that the leading agricultural journals contain but few articles dealing primarily or even remotely with the rotation and next to nothing relative to the basal philosophy of the rotation The truth is that agricultural thought in recent decades has turned ever more exclusively towards the narrow too narrow as I think path of commodities each considered as such Excessive concentration on commodities leads inevitably towards monoculture and to what we too lightly please to call specialization and leads away from the rotation and ultimately to disaster Greatly daring then I have set myself to combat this modern fetish of over concentration on commodities

Such is the precarious state of the world to day and of Great Britain in particular that there can be only one approach to the problems of agriculture and that is the national approach It so happens at least it appears to me that the present needs of the State and also the more menacing of the foreseeable contingencies unite to demand one and the same essential contribution from our agriculture It is not for me to attempt to decide whether war danger or the danger of our about rapidly to dwindle population is the greater peril little less disconcerting are the effects of soil erosion and soil depletion in those countries from which we are wont to obtain abundant and cheap supplies of food I am concerned with a long term agricultural policy the kind of policy that would take at least ten years to put into full operation and consequently we have to consider not so much immediate war danger as such a danger that owing to our island position would seem to be something from which it is now difficult to see how we shall ever escape I believe the extent of the influences of soil erosion and depletion are not even yet fully realized All methods of countering this must in the last resort react against the British housewife and must tend to increase the cost of overseas production while taking soil erosion soil depletion and land deterioration together a vaster area of the globe is undoubtedly affected than is generally supposed

The immediate and on all hands generally admitted need of our peoples is an abundance of fresh food An abundance of fresh food is not compatible with a superabundance of permanent grass Since permanent grass flows like the sea right up to the very doors of some of our largest centres of population such centres of population are automatically denied an abundance of really fresh vegetables

To sum up so far and on the strength of the various considerations I have brought forward I would say this What is demanded of our agriculture is first to maintain as large a rural population as possible for probably on a large and contented rural population depends to a marked degree the increase of our population as a whole secondly to maintain as large an acreage as possible in a highly fertile and always ploughable condition and thirdly so to conduct our farming as to allow at all times and in all places for the absolute maximum of flexibility in commodity production

Four systems of farming namely arable ley farming nondescript and permanent grass account for most of the farms of Great Britain Unless we know the number of farms and the gross acreage of such farms operating on each of these systems we know next to nothing as to how Great Britain stands relative to potential food production Furthermore schemes for helping the farmer via commodity subsidization and by planned marketing cannot be assessed in their influence on the maintenance and enhancement of soil fertility—and that is what matters above all things—unless we know the systems of farming under which the assisted commodities are being predominantly produced How much quota wheat for example is being produced respectively on arable farms nondescript farms or on ley farms ? Where is most of the milk being produced—and this is a matter of fundamental national importance in the interest alike of the health of the cattle and of the children of this country on nondescript farms permanent grass farms or on ley farms ? Where is most of the permanent grass of the country and where is the best and where the worst—on nondescript farms or on permanent grass farms ? These are all essential facts to be known in the formulation of a long term national policy for agriculture The facts are only on the land the agricultural statistics cannot give anything approaching a full answer to any one of these questions

The answer to these questions and to equally important questions connected with facilities at the farmstead and over the fields (watering drainage and the condition of fences) can only be given by a properly conducted survey carried out over the whole country and on a uniform plan Map also the type or class of all the rough grazings and permanent grass (in a manner broadly similar to the survey of Wales recently undertaken by my department) and map the ploughability of the several fields then and only then should we know where we stand To conduct such a survey would be a relatively simple matter To my mind until such a survey is put in hand and the lessons of the same—cruel and bitter the lessons will be—duly digested there is little hope that the country at large will realize either the deplorable condition of our acres or their immense potentialities The first necessity from all points of view—that of the statesman the townsman farmer and countryman in short that of the nation—is literally and in fact to put rural Britain on the map

---

* From the presidential address to Section M Agriculture) of the British Association delivered at Cambridge on August 19

Only when rural Britain is on the map shall we be able amongst other matters to decide where in the national interest it is desirable to extend arable farming and where ley farming and where it may be necessary or permissible to tolerate nondescript and permanent grass farming

In my view no problems so much as those of grass land demand prolonged and large scale agronomical investigation I would wish to distinguish between on one hand agronomical research and on the other scientific research as normally understood and conducted The major aim of agronomical research which is essentially field research is to study all the factors which are operative at once and together and in their natural interplay for nature is a theatre for the inter relations of activities Such a procedure it may be said is impossible or at least unscientific It is certainly not impossible and if it is unscientific it will yet remain agronomical and many of the problems of agriculture are more likely to be solved shall I say by agronomical investigation than by scientific research while nearly all the results of scientific research have to pass through the sieve of an immense amount of agronomical investigation before they can be made useful and in some cases perhaps before they can be other than positively dangerous to the practitioner

The technique of agronomical research entails a great deal more than blindly following all the elaborate rules and regulations laid down by the statisticians indeed such rules and regulations are of no fundamental significance in the proper planning of an elaborate series of field experiments They are sometimes but by no means always useful in the actual placing of plots on the ground and they are sometimes essential but are by no means always necessary in the examination of quantitative data One effect of the modern glorification of statistical methods has undoubtedly been a tendency to obscure the wood by the trees to concentrate on the part often an isolated part (yield for example) instead of the whole and worse still to fill the agronomist with a medley of complexes and inhibitions which have reacted adversely on the development of a technique adequate to solve a large number of the problems that can only be solved by highly complicated field experiments Many agronomists are almost too frightened to set up the sort of experiments their experiences teach should be set up because they are timorous lest the data could be made amenable to statistical analyses

Agriculture would have been the gainer if the agronomist had never been taught to be timorous and if he had plodded away undeterred and undismayed at the details of his own technique when by now perhaps he would have been able to justify his claim that what is primarily wanted to day is enormously increased facilities for the conduct of field experiments in contradistinction to field trials and demonstrations That at least is my claim for I claim to be an agronomist and in that capacity one who has been responsible for the setting up of hundreds of weird little field experiments involving in all literally thousands of plots

As always however the greatest and the final hope is the farmer himself for he at least is untrammelled by the technique of science and is not a slave to the fashions current in science while his major training is not in collecting data but in the gentle art of unadulterated observation Just because therefore of the immense accumulation of scientific knowledge so much of it but half digested in the practical sphere there has never been so urgent a necessity as at present for an abundance of well informed originally minded and affluent pioneers men willing and eager to transgress against every canon of good husbandry and to explore and almost *de novo* the whole field of rotation of crops and the whole idea of rotation of pastures of different types and of stock over the surface of the farm

I have adopted an unusual course in my approach to my subject instead of reviewing the data and evidence available I have in effect reviewed my own reactions to the implications of the work with which I have been connected for the past twenty five years and more Perhaps I need not apologize for this for after all facts and data are of no practical use until people grapple with the practical implications Instead of my facts —and scientific facts are not always correct—I have put my grapplings before you that is all and if justification is necessary I think sufficient justification is the admittedly deplorable conditions of a huge acreage of Great Britain the dilapidated condition of many of our farms and farmsteads and the therefore necessarily backward state of much of our farming Two needs seem to me to be crystal clear first the conduct of a survey on the land—and I believe every agricultural scientist though perhaps not every farmer and every economist would agree to on the land somewhat on the lines I have suggested—and then the ways and means of getting the plough into the grasslands that the survey conclusively proves ought to be ripped up Working capital and the correct expenditure of that working capital is in the last resort the only solution for our derelict and quasi derelict acres

I like the American idea of loans with a working plan of loans with advice I do not believe that the history of the years since about 1894 shows that the spasmodic periods of agricultural prosperity that have on occasion intervened have been responsible for a great deal of land improvement or for a proportionate improvement in the equipment necessary for productive farming Prosperity as such in agriculture as in industry is to a large degree a function of equipment for without the necessary equipment it is impossible to farm economically just as it is impossible to manufacture economically

Again it is unreasonable to expect that a man devoid of working capital and probably the son of a man similarly devoid should have all the knowledge of how best to farm and particularly of how best to improve land (in which art he will necessarily have had no sort of experience) in sympathy with adequate working capital suddenly provided for the purpose Advice and some measure of control must necessarily go with credit facilities and in so far as breaking up grassland is concerned I like still better the American idea of group loans and of a master borrower The master borrower in this case would be set up as a contractor with tractor and necessary equipment to break up the grasslands for it is important to remember that ploughing up of this sort is essentially tractor work that it interferes with the normal routine of an ill equipped farm while tractors are to all intents and purposes non existent in many of the districts where wholesale ploughing up is most necessary My own experiences are interesting in this connexion We tested the desire for contracting last year and had three times as many applications as we could fit into the acreage we could do while now and because of the demand our work has created locally a lorry contractor in the neighbouring village has acquired a tractor and is fully engaged on contract ploughing

I like also the American idea of being boldly eclectic and scheduling particular districts as being eligible for their rehabilitation loans There are innumerable districts that should be similarly scheduled and similarly helped in Great Britain, but always through financial help cum technical advice terminating in an agreed working plan and here again my own experience comes to support my contention for in those cases where we contracted we only did so when the farmer agreed to follow all our advice as to subsequent operations manures and seeds to the letter and in all cases the farmer has done so and demonstrably to his own advantage

The breaking up of derelict grassland is to be helped forward not only by loans but by a reorientation of such working capital as the farming community possesses and also I think by a reorientation of the monetary and other arrangements existing between landlord and tenant

Ley farming in my view affords great scope for such re orientation for it would make possible and on a general scale a variety of methods of share farming For example one might conceive of a mechanized wheat grower operating over a large number of neighbouring ley farms on a share basis another man on a share basis might be running the poultry the proprietors themselves being primarily interested in the adequacy of the rotation and farming operations and possibly in one major product—milk shall we say ? By this means farmers should achieve a better return on such working capital as is available and also the nation should achieve a more balanced specialization between farming *qua* farming and commodity production and disposal Landlords themselves could often think out with advantage methods of sharing in with their tenants and ley farming opens many avenues of approach to such sharing in but in any event it behoves the landlords of many districts to be alive to changing times and to be ready for the day—not I think far distant—when better tenants will be found for farms which are going concerns on the ley farming basis than for those which are nondescript or permanent grass It may thus prove to be a wise policy to adjust leases and even financially to assist purposeful tenants towards that system of farming which will accord best with the trend of national and international events

Let me insist in conclusion that the affairs of agriculture slowly moving as they necessarily must be are ill adapted to respond to the dictates of any immediate expediency for expediency is ever shifting and at the best is the mere shadow of what is right and true To be ever prepared for change in a world that is ever changing can be the only possible basis for a sound agricultural policy for Great Britain since we are so peculiarly liable to be crucially affected by happenings beyond our own control beyond our own jurisdiction and beyond our own borders

The Orient and Europe*

By Prof V Gordon Childe

FORTIFIED by the conclusion that diffusion from Asia to Central Europe is likely let us turn to axiom 4—the prehistoric chronology of Central Europe There the cultural sequence is reasonably clear at least north of the Bakony and the Little Carpathians The divisions which I tentatively suggested ten years ago have on the whole been fully justified by recent research But to what Oriental cultures shall these several phases be compared ? Encouraged by the newly revealed proofs of intercourse let us apply Montelius s fourth axiom to dating the Danubian sequence

The earliest bronze objects found in Central Europe (in graves and hoards of the Aunjetitz culture) include a whole constellation of specialized and arbitrary forms of ornament that are now known also in historically dated horizons Ingot torques have been found in Early Dynastic levels at Tel Agrab and recur in North Syria and in the Copper Age graves of Ahlatlibel in Turkey Earrings and lock rings with flattened ends are common in Early Dynastic Sumerian graves and in the treasures of Troy II racquet pins are found in the Royal Tombs of Ur the knot headed pin goes back to Gerzean times in Egypt and appears at Troy II its principle was applied to Sumerian toilet sets in Early Dynastic times By then tin bronze was already known to the Sumerians as to the Lesbians in the time of Thermi I In a word all the type fossils of the Early Bronze Age in Central Europe and the technical discovery that defines the period can be traced back to somewhere about 3000 B C in the Orient On the strictest application of Montelius s axiom the beginnings of the Continental Bronze Age should be nearer 2800 B C than 1800

So far as Central Europe is concerned that chronology would involve no glaring contradiction Oriental parallels can be found to the types that define earlier periods while Mediterranean shells imported even to the Rhine Valley prove intercourse with the south east right back to Danubian I Stone battle axes such as characterize period III are found already at Thermi I The Early Dynastic levels of Tel Agrab have yielded rather degenerate specimens better battle axes come from the al Ubaid settlement at Arpachiya and from Gawra VIII–IX that is equivalent to Uruk in Sumer Hence Danubian III could be equated with the Uruk period

Clay stamps generally called *pintaderas* appear in Danubian II (and in Koros sites that may be older) In form they closely resemble Asiatic stamp seals of stone and like the latter often bear a filled cross design Their distribution justifies their interpretation as copies of Asiatic stone seals But in Asia prototypes can be found so early as Tel Halaf times and in the Chalcolithic layers of Alişar and there are pedestalled bowls remarkably like those characteristic of Danubian II The upper limits for that period could accordingly be pushed back to Alişar Chalcolithic or even Tel Halaf

That is not the end of our comparisons As *Spondylus* shells were being imported from the Mediterranean even in Danubian I times so some Danubian I vases are decorated with patterns in which Neustupny rightly sees a representation of a double axe For the models he looked to Minoan Crete But double axes were used in Assyria as amulets even in Tel Halaf times So the *terminus post quem* provided by that motive can be relegated to a remote Tel Halaf period

Testing this long chronology in the other direction it can still be made to work Åberg and Reinecke have indeed insisted on Middle Helladic and Shaft Grave parallels to Aunjetitz bronzes of period IV But on the whole Middle Ægean armament—rapiers ogival daggers socketed spear heads—is typologically parallel rather to that proper to the Middle Bronze Age or period V in Central Europe A halberd from Shaft Grave IV is admittedly an Early Bronze Age type but Forssander has plausibly compared its contours with those of a Middle Bronze Age sword from Hajdu Samsón The pottery from Middle Bronze Age graves at Vattina and from south eastern Hungary includes many tankards and goblets with crinkled rims and grooved handles that might be copies of well known Middle Minoan silver vessels In a word a limiting date about 1700 B C for the Middle Bronze Age is defensible

With the fall of the Mycenaean culture we have admittedly reached the Late Bronze Age or period VI of Central Europe The barbarian invaders who sacked late Mycenaean Vardaroftsa in the twelfth or eleventh century brought ceramic traditions proper to the Late Bronze Age urnfields like Knoviz and Hötting and this date is for once a *terminus ante quem* for the Continental period An even higher limit might be deduced from the fibulæ and flange tanged swords that

---

**Continued from p 559*

appear in Greece during the thirteenth century Accordingly the following scheme of European chronology might be defended

Danubian VI (urnfield cultures fibulae and slashing swords)	1200 B C
Danubian V (Vattina ware rapiers ogival daggers socketed spear heads)	1700 B C
Danubian IV (Bronze ingot torques knot headed pins lock rings)	3000 B C

If geologists and botanists can show good grounds for demanding an enlargement and prolongation backward of the neolithic age archæological chronology can be adjusted to meet theirs without violating Montelius s axioms Danubian I admittedly the earliest neolithic culture in continental Europe would still be limited by Tel Halaf If the former have to be dated to the sixth millennium the latter can just as reasonably be assigned a like antiquity

For the moment let us adopt the maximal dates as a framework for comparing Asiatic and European cultures How would Montelius s general view of the relations between Europe and the Orient be affected by adopting the long chronology outlined here ? What happens to his fifth axiom if the Central European Bronze Age began about 2800 B C ?

By that date we should have the following picture of the tract we have been surveying We should see in Egypt and Lower Mesopotamia populous cities covering like Erech perhaps two square miles of area governed by a well established organization emancipated from immediate dependence on environmental conditions by extensive public works a rich technical equipment and regular far flung commerce and all fully literate Then in Assyria and Syria come smaller cities only slightly less richly equipped and still at least semi literate Farther afield in Anatolia and peninsular Greece are fortified townships whose walls protect a variety of specialized craftsmen so well served by regular commerce that metal at least could be freely used for tools their citizens may already need and use seals but seem to be illiterate Next in the Balkans and on the Hungarian plain we find rustic townships occupied principally by farmers Their rural economy is advanced enough to support a truly sedentary population but virtually the sole outlet in industry for the surplus is offered by metallurgical employments and trade is so imperfectly organized that metal has to be reserved mainly for armaments The same picture would apply to Bohemia and southern Germany with the important reservation that agriculture seems not to have advanced so far as to allow the population to be really stable Denmark and southern Sweden are still frankly in the Stone Age Still farther north food gathering is the sole economy

Look back as many thousand years as may be necessary to reach Danubian I times which have been for this purpose equated with the Tel Halaf period in the Fertile Crescent In the Orient we see already little townships permanently occupied by experienced farmers comprising already expert craftsmen and supplied by trade at least with obsidian In Crete and Thessaly too perhaps more self sufficient farmers are still applying sufficient science to their fields to be able to live permanently on the same site But beyond the Balkans nomadism reigns Danubian I peasants are spreading over the loss shifting their little hamlets of twenty or so households to new virgin fields every few years and beyond the frontiers of the loss are only food gatherers fishing and fowling along streams in the forest or collecting shell fish on the coasts

Yet earlier still beneath Tel Halaf villages we have glimpses of settled cultivators who judging by the few items of equipment so far recovered were at least as far advanced as the Danubians

Even on this extreme chronology Montelius s fifth axiom is justified Oriental cultures are richer than the contemporary European Moreover the first picture discloses a very significant cultural zoning As we pass north westward from the Orient we descend through regular gradations from the many sided richness of urban civilization to the stark poverty and immediate dependence on external Nature of food gathering hordes Such a grading is exactly what would be deduced from Montelius s third axiom Its discovery in the archæological record is the best demonstration of diffusion that I can imagine I take it as confirming the diffusion of bronze working with all its economic implications

But on the extreme chronology this demonstration could not be applied to food production to the more important discovery complex that made possible what I term the neolithic revolution

Montelius s thesis has come unscathed through the severest test Even on a chronology based on geological rather than archæological premises and designed to meet the demands of an extraneous discipline his axioms 4 and 5 prove workable If geologists demand dates of the order just outlined archæologists can meet them without sacrificing any essential principles but preserving intact their own proper methods and all the historically vital deductions therefrom But these high dates for Central European prehistory have been advanced provisionally simply and solely to test the applicability of Montelius s method and not as proved or even probable To justify them archæologically we have had to sacrifice many tempting comparisons and to explain away observed facts that must be admitted as relevant

Remember that down to 1200 B C no date in European prehistory could be justified archæologically by an actual object of Oriental manufacture found in Central Europe still less by an admittedly European product in a historically dated context We have had to rely exclusively on copies of Oriental models made in Central Europe Remember further that all the types on which we have relied enjoyed a long popularity in the Orient seals that could serve as models for Danubian II pintaderas were current in Crete and Asia Minor throughout the third millennium and later Battle axes for comparison to those of Danubian III were brandished equally long in central Anatolia and first appear in peninsular Greece in Middle Helladic times The type fossils of Period IV only came into fashion in the East in the third millennium and fashions did not change abruptly Knot headed pins were still being worn in the third (Hittite) settlement at Kusura during the second millennium Ingot torques racquet pins lock rings and earrings with flattened ends are common in Caucasian graves well after 1500 B C The archæological synchronisms so far considered are really just upper limits

Accordingly until geologists present their demands with more unanimity and confidence it is permissible to recall other comparisons between Central European and south eastern phenomena that entail substantially lower dates for our prehistoric periods Characteristic of Danubian II are cubical blocks of clay with one or rarely two cups hollowed out in them and perforated at the corners These have been convincingly explained as clay copies of Early Minoan block vases of stone Thus interpreted they would bring the limits of Danubian II down into the third millennium under axiom 4

Found allegedly in an Aunjetitz grave of period IV at Nienhagen in Central Germany was a clay cup its curious handle is strikingly like those of the metal Vapheio cups of Late Minoan I most popular between 1600 and 1500 B C Parallels between Aunjetitz weapons and those of the Mycenaean shaft graves of roughly similar age have already been mentioned—and explained away Still the amber beads from these and later Mycenaean graves should re enforce the arguments for a parallelism between Central European Aunjetitz and Late Helladic Greece The amber trade was a mainspring of the Aunjetitz commercial system Did it involve nothing more than barter between barbarians in Denmark Bohemia and Upper Italy ? The brilliance of the Early Bronze Age in Bohemia would become much more intelligible if that region were already connected by the amber trade with civilized Greece The probability of such a connexion is enhanced by Piggott s recognition among the amber beads from Kakovatos (Nestor s Pylos) of massive forms and space plates in the Danish style such as often occur in graves contemporary with Aunjetitz All these pointers converge upon a date for the beginning of the Central European Bronze Age a full thousand years later than the upper limits deduced from the metal ornaments

Such considerations are however frankly speculative and can if needful be dismissed It is less easy to explain away certain actual Ægean or Egyptian imports found in an apparently Early Bronze Age context in Central Europe Segmented faience beads occur in four graves near Szeged associated with pottery of the Perjamos type and in two Moravian graves with Aunjetitz pottery Though the blue glaze is generally less well preserved these beads Dr Stone assures me agree perfectly in form and technique with those from Wiltshire and from Grave 1808A at Abydos dated about 1400 B C Now admittedly the coincidence of Perjamos and Aunjetitz may not be altogether exact and Aunjetitz and Perjamos ceramic forms and even knot headed pins and ingot torques outlast the bounds of the Early Bronze Age or Danubian IV as defined by hoards But even if the relevant graves be transferred to the beginning of the Middle Bronze Age (Reinecke B) it is difficult to admit that Perjamos jugs and Aunjetitz mugs persisted virtually unchanged for 1400 years or to spread over so long a period even the 180 graves of the Szőreg cemetery from which some of our beads come

Perhaps then it may be legitimate to consider a short chronology such as I have previously advanced on several occasions as a still plausible alternative to the long one outlined here Until incontrovertible evidence from the geological or botanical side make it obsolete it is still permissible to consider in conclusion how the low dating endorsed by the fresh data just adduced affects the general credibility of Montelius s hypotheses

In our previous pictures of the Tigris Rhine tract we shall have to transpose individual items to fit a Central European chronology based on synchronisms through Greece with Egypt and altogether independent of Asia We then get two scenes both disclosing the cultural continuity and gradation recognizable only in the first picture on a long chronology At the beginning of the Central European Bronze Age towards the middle of the third millennium B C the picture would be much the same as that already sketched

Fifteen hundred years or so earlier the gradations would be similar, but the zones would have contracted. We should see:

(1) In Egypt and Mesopotamia true cities the walls of which may already enclose nearly two square miles relieved from immediate dependence on environmental accidents by public works and organized commerce, comprising a variety of artisans and officials including scribes.

(2) Smaller cities in Syria less richly equipped and only partially literate.

(3) Copper Age townships in Anatolia and peninsular Greece with a walled area of two to four acres and a population comprising specialized smiths and some other craftsmen adequately provided by trade with metal and other raw materials.

(4) In Thessaly, Macedonia and the Morava-Maros region beyond the Balkans neolithic villages are permanently occupied by experienced farmers who are content to do without metal.

(5) North of the Maros-Koros herdsmen and Bukkian troglodytes are grazing and tilling patches of loess and then moving on; still farther north Danubian I hoe-cultivators are shifting their hamlets of twenty odd huts every few years to fresh fields until they reach the confines of the loess.

(6) Beyond these on the North European plain are only scattered bands of food-gatherers hunting, fowling and fishing and collecting nuts or shell-fish.

In each picture we see within a continuous area of interlocking cultures gradations such as would be deduced from the diffusionist postulate. But a comparison of the second picture with the first reveals just that expansion of the zones affected by the neolithic revolution that would be anticipated were its effects being indeed diffused. The acceptance of axiom 4, the rigorous application of his chronological method alone would virtually allow the graphic demonstration of Montelius's remaining assumptions.

Obituary Notices

Prof. Samuel Alexander, O.M., F.B.A.

WITH the death of Prof. Samuel Alexander in his eightieth year we have lost one of the few creative thinkers of our day. At the end of the nineteenth century many believed that all philosophical systems had been thought of so that there could be no *new* ones and that, as hitherto no British philosopher had ever produced a system, none ever would. Alexander's work refuted both these beliefs.

It has been customary to call his philosophy realist as opposed to idealist, but it is not so easily classified. It is true that he revolted against the Hegelian tradition he was trained in, but even more he revolted against that wider tradition, not necessarily idealist, that makes the theory of knowledge the central and almost the only topic of philosophical discussion. For those of the tradition, the sole starting point of philosophy is the individual conscious mind, and knowing is its unique relation with the world, if there is one. For Alexander the starting point is the world as known; knowing is not a unique relation but is common to all related beings that 'prehend' each other, to use Whitehead's term. As a conscious being I 'enjoy' my activities as knower, but this 'enjoyment' is strictly irrelevant to any discussion of what is known. The iron 'knows' the magnet but does not 'enjoy' it, for it lacks the privilege of consciousness. The spider 'knows' the fly and incidentally may or may not 'enjoy' it, and so *mutatis mutandis* does the fly. The starting point then is the world as known, and Alexander finds its universal substratum or matrix to be space-time, which includes minds and bodies and everything. Bergson helped Alexander to realize that time cannot be left out as a regrettable imperfection, and the mathematical physicists that space and time separately are not primary. Time is related to space much as mind is to body. The main task of philosophy is to point out and classify the recognizable features of space-time, that is to say, the categories. The world as we now see it is the result of a process of development such that there is a hierarchy of natures. Of these the higher can understand the lower but not the lower the higher. Minds are the highest natures we are acquainted with. There is potentially a higher stage in the hierarchy towards which the universe may be said to be striving: this is deity. It is deity that is the end of moral progress and the object of religious worship.

Alexander himself said that his philosophy was Spinoza's "with Time put in". There are, in fact, many resemblances between these two Jewish philosophers and their philosophies. For both of them philosophy must begin with the results of the natural sciences, but must go beyond them to make their crown and completion. Unless in this process philosophy becomes theology and moral theory, it is nothing. Alexander realized, as did Kant, the further point that a philosophy with a naturalistic basis must come to terms with man's sense of beauty and artistic activities. In his later years he was occupied mainly with these problems.

The external events of Alexander's life can be briefly told. He was born in Sydney, New South Wales, in 1859; like Kant, the son of a saddler. He went to Wesley College, Melbourne, then to the University of Melbourne, and in 1878 won a Balliol

Scholarship. At Oxford he performed the unusual feat of a first class in both Classical and Mathematical Moderations before taking a first in Greats in 1881 In the following year he was elected fellow of Lincoln College, where he remained until his appointment to the chair of philosophy in Manchester in 1893 He held this chair until his retirement in 1924, and he stayed faithful to Manchester to the end of his life As presenter for honorary degrees until 1930 and as honorary professor he kept in close touch with the University. He lectured frequently in Manchester and elsewhere as long as his strength allowed The University of Manchester possesses a fine bronze bust by Epstein which has preserved the severe beauty of his bearded head, but leaves the beholder to guess the kindliness and humour that were also visible in life

Alexander's philosophical writings are none of them 'popular' and are not to be read without intellectual effort ; but given that effort they are found to be clear and straightforward and free of unnecessary technicalities. His first book, "Moral Order and Progress" (1889), which was awarded the Green Moral Philosophy Prize, was written before he developed his characteristic views The long interval between this and the appearance of his chief work, "Space, Time, and Deity" (1920), filled with only one small book on "Locke" (1908), represents the incubation period of his philosophy The first expositions of his views, in short papers from 1907 onwards, appeared at the time to be excessively paradoxical and made little impression The invitation to Glasgow as Gifford Lecturer in 1916–18 was therefore well timed to induce him to develop his whole system in one comprehensive work Later books are · "Spinoza and Time" (1921), "Art and the Material" (1925), "Beauty and Other Forms of Value" (1933) His numerous papers in the *Proceedings of the Aristotelian Society*, *Mind*, and other journals have not been published in book form

In spite of his deafness, Alexander was the most sociable of men He never forgot old friends and continually made new ones People of all kinds and all ages were equally drawn to him He was a witty speaker on social occasions, and his technique in presenting honorary graduands will long be remembered : a dexterous mixture of information and compliment spiced with gentle malice. The various honours bestowed on him of late years gave him unaffected pleasure they merely confirmed his modest belief that people were kinder to him than he deserved. Though all his life a poor man who spent more on others than himself, during the last few years he gave to the funds for Jewish refugees as though his wealth was unlimited

At the end, Alexander was ready and even glad to die, tired perhaps of a world where the insane persecution of his people has begun again, and where the reason and humanity in which he had put his faith seem to be fighting a losing battle A D R

WE regret to announce the following deaths :

Sir Philip Dawson, a distinguished electrical engineer, who received the George Stephenson Gold Medal of the Institution of Civil Engineers and also the Albert Medal of the Royal Society of Arts, on September 24, aged seventy-one years

Lord Marks, known for his work in civil, mechanical, hydraulic and electrical installations, and founder of the firm of Marks and Clerk, patent agents, with which the late Sir Dugald Clerk was associated, on September 24, aged eighty years

News and Views

Development of Museums and Galleries

THE Standing Commission on Museums and Galleries, of which Sir Evan Charteris is chairman, has just issued its second report, covering the five years 1934–38 (London · H.M Stationery Office, 1938 9*d* net) The Commission was appointed in 1931 to advise generally on questions relevant to the most effective development of the national museums and galleries of Great Britain The report surveys the very considerable building developments which have taken place in the period under review and directs attention especially to the part played in this by private benefactors : Lord Duveen's provision of sculpture galleries at the Tate Gallery, and one for the Elgin Marbles at the British Museum ; also Sir James Caird's benefactions to the National Maritime Museum at Greenwich, and the gifts made by Sir Alexander Grant to the National Library of Scotland, are referred to. The Commission was invited by the Treasury to advise on the general proposals for future building schemes, which would cost some £1,000,000, and to indicate an order of priority for them Its recommendations, which it is understood have been accepted, provide for the entomology block of the Natural History Museum (second half), and the lecture hall for the Royal Scottish Museum being begun in 1938 and completed in 1939 These are to be followed by the central section of the Science Museum in 1940, the northern wing of the Natural History Museum in 1941, and the Museum of Ethnography in 1942, these being completed in from two to four years.

THE Commission has also been asked to advise on the future development of the site at South Kensington, which has of late been under consideration and was discussed in a leading article in NATURE of September 17. Final plans are not yet available and they will need careful consideration and discussion, nevertheless, more adequate accommodation for the collections of the Science Museum seems at last to be in sight The formation of a collection of ship models at the National Maritime Museum has raised the question of what should be the appropriate spheres of this Museum and the Science Museum in representing naval architecture, the Commission has gone carefully into the matter and has proposed certain broad principles of development which it recommends for future guidance The abolition of fees for admission to museums and galleries, where these are still imposed, is strongly recommended

Man or Gannets

A CIRCULAR letter, signed by Sir Montagu Sharp chairman of the Royal Society for the Protection of Birds, and Mr John M Crosthwaite, honorary secretary of the Scottish Society for the Protection of Wild Birds, has been received by NATURE and has been widely circulated in the daily newspapers It states that the inhabitants of Lewis capture and preserve for winter food some two thousand nestling gannets, after a journey over some 40 miles of open sea to the uninhabited islet of Sula Sgeir sarcastic comment is made on 'the apparent plight of the inhabitants . that of necessity they have to eat Gannets', and suggests that this wilful destruction of these birds for human food should be stopped The letter further states, inaccurately, that such slaughter is without precedent in Great Britain This is scarcely correct Historically, the use for human food of the nestlings of the birds which frequent certain bird rocks in Scotland in great numbers is an ancient practice which throughout centuries has made no appreciable difference to the bird populations In Edinburgh the nestlings of gannets from the Bass Rock used to be sold in the streets, as a luxury and not as something which suggested the plight of starvation or lack of 'sufficient food of a more ordinary and palatable kind', as the signatories describe it At the time when St Kilda was most prosperous, its people preserved and fed annually upon, not two thousand, but many thousands of fulmar petrels, and if the stoppage of that source of food supply has had any effect upon the fulmar population, it has been to threaten to make that bird a nuisance on certain parts of the coast of the mainland

THE circular states that in order to bring about the protection of gannets of Sula Sgeir, the County Council was approached by the signatories or the societies they represent and 'urged" to take the necessary action to make this island a bird sanctuary, so that the men of Ness could be prosecuted if they took the birds The County Council refused to take any steps in the matter on the grounds that the gannets constituted in money and food a great aid to the livelihood of the people of Ness Presumably the County Council, composed of local representatives, knows what it is talking about, and presumably some urge greater than useless destruction causes these crofters of Ness to cross forty miles of the open Atlantic and to spend an uncomfortable fortnight on an isolated island collecting these winter food stores But a curious situation has been reached when sentimental regard would insist that the welfare of birds should be preferred to the welfare of human beings

Influence of Science on Current Thought

THE fifth lecture of a series on the influence of science and research upon current thought, established by the Carnegie Institution of Washington in honour of Mr Elihu Root, who was, until his death last year, a member of the board of trustees of the Institution and its chairman during the last twenty-four years of his life will be delivered by Sir Richard Gregory in the Institution s new auditorium on December 8 The subject will be Cultural Contacts of Science , and the lecture will, therefore, be concerned mainly with associations of science with religion, literature and other aspects of intellectual development and social evolution, rather than with the services rendered to modern communities by utilitarian applications of scientific knowledge As Mr Root was deeply interested in the relation between the advance of science and development of human values, it is appropriate that this should be the general theme of the series of lectures bearing his name The lectures are published in book form after their delivery The subject of the fourth lecture in the series was The Concept of Uniformity Growth and Reactions , by Dr F H Seares, assistant director of Mount Wilson Observatory

Roman Dorchester

ON September 26 the foundation stone of the new Shire Hall in Colliton Park, Dorchester, was laid by Lord Shaftesbury This building is probably unique in Great Britain in that it is the first to be erected on the site since Roman times, and also because there will stand near by permanently preserved, one of the residential buildings of the Roman town of Durnovaria, brought to light by the excavations of the Dorset Natural History and Archæological Society, which were initiated under the direction of Lieut-Colonel C D Drew when attention was directed to the existence of Roman remains at this point by the preparations for building Further discoveries are still being made Colonel Drew records the discovery of a fine tessellated pavement of geometrical design It had been broken in ancient times, and in the fracture was found a delicate Roman balance in bronze, which probably had been used for goldsmith's work The beam was three inches long only One of the pans was intact, the other in fragments The pavement is to be removed to the adjacent Roman dwelling, and the balance has been set up in the Dorchester Museum Further work in the examination of the neighbouring town wall in the North Walk reveals that on this side there was no stone wall, such as was found recently below Colliton Walk Here an earthen rampart had the natural reinforcements of the river and marshy ground

Archæological Excavations at Colchester

Systematic archæological excavation on the central part of the site of the ancient British city at Colchester must, it is announced, cease permanently at the close of October, when this area of some twenty acres is to be developed for building. It will be remembered that the discovery of a British settlement here was made eight years ago in the course of preparations for the Colchester by-pass road; and that since that date, with the co-operation of the local authorities, a Committee of Excavation, under the auspices of the Society of Antiquaries of London, has been engaged in the archæological exploration of the site. Not only has the defensive system been investigated, but also a very large number of antiquities, estimated at something in the neighbourhood of a million, and including fifty tons of pottery, has been recovered. This site has, in fact, proved one of the most prolific of ancient British sites yet examined. The central area now under examination, it was hoped, would afford some evidence of the place of residence of the British king, Cunobelinus, but so far nothing of this nature has come to light. Among the more important objects recently reported in the present season's work are an iron box four inches square and one and a half inches deep. This contains a powder believed to be a pigment used by the potter. A Roman dagger, 15 in. long, has also been found. Although systematic investigation must cease as soon as building operations begin, local members of the Committee will continue to oversee the work of foundation-digging in the interests of archæology.

Burials of Saxon Age in Kent

One of the most important discoveries of burials of Saxon age in recent years is recorded from Risley, Horton Kirby, four miles south of Dartford, in Kent. In the course of road-making on the housing estate of the District Council, burials were brought to light in which were human bones, spear-heads, the umbo of a shield, pottery fragments, and an almost complete glass vessel. Fortunately the finds were brought to the notice of the Dartford Antiquarian Society, and their character as Saxon or Jutish recognized. Further excavation made it evident that this was the site of an extensive cemetery, although another, excavated in 1867, existed only a mile away to the north. That the present site had been in use for burial purposes even before Saxon times was indicated by a Roman cinerary urn and a circular cist burial. The prevalence of inhumation points to a Jutish origin, the period of the burials being from the sixth to the ninth centuries of our era. The people must have been of exceptionally fine physique, as a number of the skeletons are those of men more than six feet in height. So far more than seventy graves have been exposed. The burials as a rule are shallow, not more than two feet deep. In one instance only have valuables been found—in the grave of a woman, in which were five gold brooches and four beads of amethystine quartz. The brooches, it is stated in a report on the excavations in *The Times* of September 16, were circular, of filigree work, with precious stones inset, and represent a style of ornament peculiar to Kent, of which this is the westernmost example. One fine burial of a warrior with shield-umbo, sword and spear, is to be removed and reassembled complete, with the bones, for exhibition. The excavations are being continued on a part of the site which is to be set aside as an open space. A selection of the finds has been on view in the Dartford Borough Museum.

Meare Lake Village

The three habitations (Nos. xx, xxii and xxiv), which have been examined by Mr. H. St. George Gray and Dr. Arthur Bulleid in the course of the current season's investigation of the eastern division of Meare Lake Village, Somerset, by the character of the finds, more particularly those in hut No. xxii, have emphasized both the importance of the weaving industry in the economy of the inhabitants, and their appreciation of personal ornament of a colourful type. In hut xxii, in which five superimposed hearths of stone and clay have been uncovered, no fewer than twelve combs for beating down the weft and woof threads have been found, with bobbins, loom weights and a dozen spindle-whorls of stone, bone or baked clay. Among other finds were half a dozen saddle querns, hammer-stones and whetstones, a polished flint axe converted into a hammer, flint scrapers, bone awls and modelling tools, iron tools, bone gouges and handles and other objects of red and roe-deer antler, including a 'gaming piece'. A scapula, or shoulder-blade of ox, is ornamented with the dot-and-circle pattern. By far the largest series of remains, however, it is stated in a report on the excavations in *The Times* of September 16, may be classed as personal ornaments. These include two toggles or dress-fasteners, one finely engraved with four rows of dot-and-circles, the other of a zoomorphic character, having one end resembling the head of a fish. A remarkable large flat brooch is of bronze, of which the surface was probably inlaid with enamel. The finest of the armlets of Kimmeridge shale is carved, while jet appears in the village for the first time in the form of a bead. Another bead of amber has been found, and beads of glass are numerous, the colours being blue, dark red, yellow and black. Some of the beads of clear glass ornamented with yellow spirals were found in a group. The smallest beads (blue) are only two millimetres in diameter. Canine teeth of the dog had been pierced for suspension as a necklace. In hut xxii more pottery, mostly cooking wares, has been found than in any other dwelling.

Twenty Years of Polish Science

When Poland regained its independence in 1918, a new impetus was given to Polish science and culture, which had had to struggle against adverse conditions for so long. The present year marks the completion of twenty years of constructive achievement in many directions. Much that has been achieved in general science has been recorded in *Nauka Polska*, a comprehensive publication issued at least once annually by the Mianowski Institute for the Encouragement of Science in Poland, which is concerned with the history, organization and co ordination of scientific effort The recently published volume for 1938 (No 23) includes in its 400 pages contributions by several leading Polish men of science Thus, Prof B Kieskowski discusses the question whether philosophy can be considered as a science, and gives cogent reasons for an affirmative answer Prof W Semkowicz has two lengthy contributions, the first being devoted to a comprehensive account of scientific and philological work at Cracow, the seat of the Polish Academy of Sciences and of the Jagellonian University, since the establishment of the republic The second article is a survey of the special needs of science to day There is an informative description, by Dr W Siemaszko, of recent advances in phytopathology both in Poland and elsewhere This branch of applied botany is of special significance to a country like Poland, which has a large agricultural industry as well as extensive forests Particular attention is given to the organization and co ordination of research, and reference is made to the facilities for planned researches in Poland, Czechoslovakia, Britain and America Of immediate interest, too, is a contribution by Dr J Gołabek on Polish cultural facilities in Czechoslovakia and the collaboration between men of science in these two Slav countries A section devoted to reviews makes reference not only to books, but also includes résumés of articles that have appeared in scientific periodicals This volume of *Nauka Polska* concludes with a bibliography of works dealing with the 'science of science' for the years 1935 and 1936

National Museum of Canada

THE annual report for 1936–37 of the National Museum of Canada marks good progress, particularly in the resumption of field investigations During the summer of 1936, field parties were engaged in biological work on the Pacific coast, ornithological investigations in Manitoba, a special biological survey of Thelon Game Sanctuary, botanical surveys in Ontario and the Arctic, archæological excavations in Ontario and the Arctic, anthropological studies of French-Canadian art and handicrafts, and the effect of the contact of the white man upon Indian culture As a result, much material has been added to the collections and scientific information of value has been obtained To the naturalist, one of the most interesting investigations is that mentioned in Dr R M Anderson's report on the work of the Biological Division A survey is being made of the region about Horseshoe Lake, which was burned over about a hundred years ago and now shows the conditions that follow natural reforestation in British Columbia Now these blocks of second growth timber are acting as reservoirs of wild life, islands of refuge in the midst of a country which had been burned so that all small wild life was destroyed For long stretches the burnt area showed no trace of a mammal, and the destruction of mossy ground, cover and rotten logs removed such as weasels, shrews, snakes, frogs and slugs. From the protection of the natural refuges the fauna is beginning to recolonize the burnt-out regions.

A Century of Sociology

IN the R R Kale Memorial Lecture 1938 to the Gokhale Institute of Politics and Economics, Prof C S Ghurye reviewed the social process in the light of a century of sociology Social process, he considers, has two aspects the nature of cultural development as reflected in the trend of thought about man as a living entity, and the process by which the individual is assimilated into the cultural flow of the times Although Protagoras gave effective currency to one of the fundamental requisites of science—to take experience as the only category strictly knowable for the human intellect—the ethical outlook afterwards overshadowed or eliminated the scientific spirit, and Prof Ghurye considers that it was not until Montesquieu that human experience was again viewed with the eye of a man of science In his argument, the force of human motives first received real recognition Stressing the significance of the English contribution to the advancement of knowledge on the Comtian plane, he pointed out that the social life of man is becoming the centre of attraction and motivation the principle of explanation The psychology of motivation found its scientific liberator in Shand, who sought the explanation of human motivation in the social behaviour of man and not in his biological activity

SCIENTIFICALLY, the proper planning of a good life must rest on the understanding of life and the psychological study of the individual and society should precede the study of man as a political and a moral being In conclusion, Prof Ghurye, discussing the institution of marriage, urged that in view of the importance of the first few years of the individual s life in the social process, if accommodation of the individual into his social mould was to be smooth and harmonious, the environment in those years must be provided by a small group, the individual constituents of which are highly sympathetic Such a group is only ideally provided in the family unit Prof Ghurye made an earnest plea for the institution of a chair of sociology in the Gokhale Institute

Photographic Reproduction of Documents

AN exhibition is being held at the Science Museum, South Kensington, of many types of apparatus for the photographic reproduction of documents, suited to both occasional and extensive use, and adapted to varied requirements It comprises several original types of cameras and projectors, suitable for amateur and professional use Some of the apparatus is arranged to utilize standard commercial general utility miniature cameras Other cameras shown are designed specifically for the purpose of book reproduction—in whole or in part—in reference libraries, together with the corresponding projecting apparatus for magnifying the film images to enable natural size or enlarged images to be viewed or prints to be made Finally, there are exhibits illustrating the use of photographic apparatus specially designed to provide at cheap rates both single and multiple copies of documents without reduction of their natural sizes The exhibition, which has been arranged in conjunction with the recent meeting of the International Federation of Documentation will remain open to the public until October 31

History of Luchon

IN his inaugural dissertation on Luchon (*Thèse de Paris*, 1938, No 497), Dr P J M J Molinéry gives an interesting historical account of this celebrated health resort situated in the heart of the central Pyrenees He describes three distinct stages in its development namely, the Gallo Roman epoch, the eighteenth and nineteenth centuries and modern times In antiquity, Luchon enjoyed a high reputation owing to the Aquæ Onesiæ, which were recommended by Oribasius and Antyllus among others for nervous and gastric disorders, skin diseases and rheumatism Then followed a period of more than a thousand years when Luchon fell into entire oblivion In the eighteenth and nineteenth centuries it recovered something of its former splendour Fresh bathing establishments were built over the Roman ruins and new springs were discovered During this period, Luchon was specially recommended for the treatment of skin diseases, rheumatism, menstrual disorders scrofula and syphilis In the twentieth century it became not only one of the most important of the Pyrenees sulphur stations but also one of the most radioactive centres in Europe The diseases treated at Luchon at the present time are mainly disorders of the respiratory tract, deafness of nasal origin, rheumatism, skin diseases and secondary and tertiary syphilis

Annual Report of the Ministry of Health

THE principal vital statistics and the health services for England and Wales in 1937 are surveyed in the recently issued nineteenth annual report of the Ministry of Health 1937–38 (London H M Stationery Office 5*s* net) The estimated mid year population was 41,031,000, the live births were 14 9 and the deaths 9 3, per 1,000 population Maternal mortality in 1937 was at the record low level of 3 11 per 1,000 births, and great efforts are being made to reduce still further this distressing cause of death The infant mortality rate was 58 per 1,000 live births, the lowest on record with one exception (1935) The death rate from all forms of tuberculosis was 657 per million population and the various measures and schemes for the reduction of tuberculosis mortality are outlined Only four cases of smallpox were notified during the year, but 55,896 cases of pneumonia were notified, compared with 46,167 cases the previous year The increase appears to be attributable in part to an outbreak of influenza in the earlier part of the year The notified cases of diphtheria were also more numerous than in 1936, but scarlet fever incidence was lower Cancer deaths numbered 66,965, remaining much the same as in the previous two or three years Much is said on housing and slum clearance, and 337,616 houses of a rateable value not exceeding £78 were completed during the year The Ministry of Health Vote for 1937–38 amounted to the net sum of just over twenty-two million pounds

Liverpool Naturalists' Field Club

THE seventy seventh *Annual Proceedings of the Liverpool Naturalists' Field Club* for the year 1937, recently issued, contain a comprehensive summary of the year s fauna and flora in the Merseyside and Deeside areas, in addition to Mrs R Laverock's presidential address on Defences and Adaptations in Plants', and résumés of the general field meetings of the year at local places of interest The botanical records, compiled by Mr J D Massey, include a number of new district records Insect records are summarized by Mrs Makinson, the entomological referee A comprehensive month by month summary of the bird records by Mr Eric Hardy, the ornithological referee, includes the occurrence of greenshanks, ruffs, peregrines, curlew sandpipers, green sandpipers the sabine s gull and little gull in the area, the increase of nesting tufted ducks, teal, redshanks, and lesser black backed gulls the results of surveys of magpie coot and red backed shrike distribution carried out for the British Trust for Ornithology, and the nest counts at the rookeries and heronries in the district The Society is increasing the number of prizes offered for natural history work during the year to nine

Research at King's College, Newcastle-upon-Tyne

FOLLOWING on the reconstitution of the University of Durham, involving, as it did, the amalgamation in King s College of the former Armstrong College and the College of Medicine, the Standing Committee for Research established in 1923 in Armstrong College with an endowment of £12,000 has been reconstructed so as to include representatives from the Medical School The Standing Committee s report for 1936 37, which gives particulars of twenty four grants, amounting in the aggregate to £900, made during that session, announces the provision of a senior research fellowship tenable during 1938–39, to enable a member of the staff of King s College to undertake research upon a specific problem necessitating complete absence from teaching duties The report shows no signs of diminution of research activities in any department of the College Conspicuous among them have been the Siwa Oasis Expedition, in respect of which Mr J Omer Cooper received a grant from the Committee, Mr R F Peel's investigations of sand formations and the movement of dunes in the Libyan desert, and botanical and zoological researches in the Hebrides

Scientific Work in Moravia

BRNO (Brunn), the capital of Moravia and the home of Mendel, has good facilities for scientific research Besides the Masaryk University, founded in 1919, there are the Czech and German colleges of technology and also medical, veterinary and agricultural schools All these are staffed with specialists engaged in directing research as well as in teaching The results of their investigations are mostly published in the *Spisy vydávané Přírodovědeckou Fakultou Masarykovy University* (Publications of the Faculty of Sciences of the Masaryk University), edited by Prof A Šimek, or in the periodical *Bulletins* of the various colleges and in the *Proceedings* of the Moravian

Scientific Society In this way all branches of the natural sciences in Moravia are represented in publications which reflect the high standard of work performed by contemporary Moravian men of science, including discoveries in archæology, geology, ecology and biology in addition to meritorious physico chemical researches

Mercury Poisoning

A REVIEW of present knowledge as to the liability of users of mercury to contract mercury poisoning by continued exposure to mercury vapour or to solutions of mercury compounds of small concentration has recently been issued (*Rev Sci Inst* Aug) Although there are great differences in the sensitivity to poisoning amongst individuals, it seems certain that prolonged exposure to an atmosphere containing one quarter of a milligram of mercury vapour per cubic metre of air is dangerous As the saturation vapour pressure of mercury at 18° C is such that there is more than 10 mgm of mercury in a cubic metre it is evident that exposure of considerable surfaces of mercury to air at ordinary temperatures should be avoided Good ventilation is the best precaution where exposed surfaces are unavoidable, and this failing, gas masks containing carbon iodine absorber should be used Rubber gloves should be worn to prevent contact with mercury or mercury solutions

Optical Utilities

MESSRS W WATSON AND SONS LTD 313 High Holborn London, W C 1 have issued a booklet entitled 'Optical Utilities containing a catalogue of small optical instruments for aiding vision These include magnifiers mounted as spectacles, the Speera ' for dissecting or viewing minute objects, and the Spectopera" for viewing distant scenes, a magnifying glass with electric bulb in the handle for examining maps prints, etc , a Strip magnifier for reading small print, a pocket lens compass, the needle of which is mounted between two lenses so that it can be used as a pocket magnifier, and other useful devices

Noise Insulation

THE valuable summary of the best methods of reducing noise which Dr G W C Kaye of the National Physical Laboratory, communicated to the *Journal of Scientific Instruments* in June has now been issued by the Institute of Physics as a separate publication, and should be in the hands of all designers of structures in which noise is to be diminished as much as possible The loudest of the offending noises should first be reduced at least to the average level of the others, either by reducing it at its source or by providing fewer facilities for its propagation Against direct transmission through the air the remedy is to enclose the source or hearer in a sound proof building, which may require its doors, windows, walls and floors to be heavy or double with intervening air gaps, and to have its walls and ceilings lined with sound absorbing materials Metal piping should have short lengths replaced by rubber or other less efficient transmitting material, and be supported by insulated clips.

National Research Council of Japan

THE report of the National Research Council of Japan for the year April 1936–March 1937, which has recently been published, contains a list of serial publications issued during the year, with details of the general meeting divisional meetings and committee meetings as well as of the international scientific meetings at which the Council was represented In addition to the Divisions of Astronomy Geophysics Chemistry Physics Geology and Geography, Biology and Agriculture, Medical Sciences, Engineering and Mathematics, a Committee of Pacific Investigation has held five meetings and a National Committee on Radio Research ten meetings dealing with the transmission of short waves, measurements of radio waves during the total solar eclipse on June 19 1936 studies of the ionosphere etc The report also gives the personnel of the various divisions and committees and a full list of serial publications received from abroad

Political and Economic Planning

A BROADSHEET recently issued by P E P (Politica and Economic Planning) summarizes the progress o P E P in 1936–38 In the last two years the volum of published P E P work has approximately doubled, five full reports covering electricity supply international trade social services health services and the Press having appeared within sixteen months besides more than thirty regular numbers of *Planning* This result has been attained by a small voluntary body with a budget of less than £10 000 a year and a paid staff of less than a dozen persons This in itself is a striking indication of the opportunities which exist for organized thought about the future, and the most significant feature about the work of P E P is probably the extent of the opportunities it has opened up The results already achieved suggest that by bringing to bear on public problems even a small proportion of the available intelligence and energy it should be possible to prevent serious national and international difficulties from arising The broadsheet gives a complete list of reports already issued as well as of the planning broadsheets, and indicates the position of the studies of regional development and industrial location, on the gas industry, on partners in industry and of the inquiry into population policies which have been initiated by P E P and on which reports are later to appear

Science for the People

ADVANCE reports promise that science will be well shown at the great 1939 exhibitions in America—the Golden Gate International Exposition in San Francisco and the New York World s Fair (Science Service, Washington, D C) Synthetic foods will be manufactured on the spot, and laboratory rats will be fed upon the foods, and have to stand a comparative test against normally fed individuals A complete 'chemical' garden growing indoors, without sunlight and without soil, will illustrate the production of maize, peas, melons, squash, spinach and lettuce by chemical means and ordinary incandescent lighting Electrical apparatus, television, sound amplifying equipment, at which the visitor will be able to listen to the footsteps of insects, promise to enlighten the populace regarding the more spectacular aspects of scientific discovery It is noteworthy that the site of the New York Fair, which used to be a dismal swamp outside Flushing, Long Island, has been converted into turf, suitable for planting the 10,000 trees taken to the place, by chemical treatment of the acid swamp soil

Current Sunspots

A FAIRLY large single sunspot of area about 700 millionths of the sun's hemisphere crossed the sun's central meridian on September 25 6 in latitude 10° S This was followed by a larger group of stream type which is crossing the disk between September 21 and October 4 in latitude 12° S, the time of central meridian passage of the group centre being September 27 7 The area of this big group on September 23 was 1,800 millionths of the sun's hemisphere Spot groups as large as this are more often than not associated with terrestrial magnetic storms, the average time of commencement being about one day after central meridian passage Two striking examples of the activity of this region of the sun's chromosphere were witnessed at Greenwich on September 20 and 22 with the Hale spectrohelioscope working in $H\alpha$ On September 20 at 14^{h} 38^{m} U T, a highly eruptive prominence was observed to spring from this region then passing into view at the sun's east limb The prominence was unusually brilliant, a photometric measure at 14^{h} 41^{m} giving a central intensity of 66 per cent (where continuous spectrum 10 A from the centre of $H\alpha$ at the centre of the disk = 100) There were big differences of measured radial velocity amounting to 225 km /sec between adjacent filaments at 14^{h} 54^{m} The prominence rose from its point of origin to a height of some 4′ (175,000 km) within 15 minutes On September 22, an extensive absorption marking on the disk, representing the projected image of a prominence, was observed at 8^{h} 50^{m} with a velocity of ascent exceeding 260 km /sec This marking, with both ascending and descending filaments, extended as seen in projection over some 150,000 km of the chromosphere and partly encircled the leader sunspot Activity persisted for at least 3½ hours

The Night-Sky in October

SUMMER Time ends on October 2 at 2^{h} U T The moon is full on October 9 at 9 6^{h} (the Hunter's moon) and new on October 23 at 8 7^{h} Lunar conjunctions with the planets occur as follows On October 5^{d} 11^{h} with Jupiter, October 9^{d} 12^{h} with Saturn, October 21^{d} 4^{h} with Mars, and on October 26^{d} 0^{h} with Venus On October 12^{d} at 9^{h}, Mars is in conjunction with Neptune The planet Jupiter is the dominating bright star of the evening skies, in mid-October it souths at about 20^{h} The various phenomena of the four inner satellites may be followed with the help of data given on pp 618–619 of the *Nautical Almanac* for 1938 or in abbreviated form [illegible] p 170 of *Whitaker's Almanack* On October 16, Venus is at greatest brilliancy, but the planet sets 43 minutes after the sun Saturn is on the southern meridian at about $23\frac{1}{4}^{h}$ in mid-October, on October 8, it is in opposition, the distance from the earth being about 781¼ million miles Mars is a morning star rising at $3\frac{3}{4}^{h}$ in the middle of the month Two well known variable stars are now well placed for observation during the late evenings o Ceti, the variability of which was first recognized by Fabricius in 1596, is a long period irregular variable At maximum the star is usually of magnitude 3 or 4, but is occasionally of magnitude 2, at minimum it sinks to magnitude 9 The period is about 330 days A maximum is expected near the beginning of October The other variable, Algol (β Persei) is an eclipsing binary the periodic variations in brightness of which were discovered by Goodricke in 1782 as occurring at regular intervals of 2 days 20 hours 49 minutes There are several meteor radiants listed for October, the Orionids are seen at a maximum during October 18–20 On moonless nights, the great nebula in Andromeda, visible to the naked eye, may easily be located with the help of binoculars The Pleiades are now well above the eastern horizon in the late evening

Announcements

THE RIGHT HON THE EARL OF ATHLONE, Chancellor of the University of London, will open the new buildings of Queen Mary College on October 12 at 3 p m

SIR MALCOLM WATSON will speak on "Malaria and Empire Development" at a joint meeting at 18 Northumberland Avenue, London, W C 2, of the Planters' and Empire Social Services' Groups of the British Empire Society on October 6 at 8 p m

DR H T CALVERT, chemical inspector at the Ministry of Health, will open a discussion on the present trend of sewage purification at a meeting of the Royal Sanitary Institute, 90 Buckingham Palace Road, London, on October 11 at 5 30 p m

THE Danish Institute for Human Heredity and Racial Hygiene at Copenhagen is to be incorporated in the University under the direction of Dr Kemp.

17,330 persons have recently died of cholera in the United Provinces in the north of India during an epidemic reported to be one of the worst for many years Bodies of victims are thrown into rivers that supply drinking water, and religious Hindus, many infected with cholera, continue to bathe in the Ganges Mass inoculation of exposed persons and disinfection of dwellings have been carried out

A NEW law has recently been passed in the Argentine Republic of which the principal enactments are (1) the abolition of licensed prostitution, (2) compulsory treatment for venereal disease, (3) penalties for wilful transmission of venereal disease, (4) prenuptial medical examination, which is compulsory for men and optional for women, (5) prohibition of quack advertisements for the cure of venereal diseases.

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 620.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Transition Temperatures of Superconductive Alloys

THE transition between the normal and the superconductive state of a metal is a phase transition of the second kind, that is, there is no latent heat but a discontinuous jump in the specific heat, as at the λ-point of liquid helium or at the Curie point of a ferromagnetic. At the transition temperature in such phase changes, the entropy of the two phases as well as the free energy is equal. Thus if the entropies of the superconductive and the normal states are plotted as functions of the temperature T, the intersection of these curves determines the transition temperature. In the normal state the entropy is known to depend linearly on T at low temperatures The entropy of the superconductive state can be determined from the magnetic threshold curve[1] and is found for most superconductors to vary approximately as T^2. There is a fairly well established theory which gives the entropy in the normal state, and we can predict with fair certainty how this will change when small quantities of other metals are added in solid solution It is the purpose of this letter to show that the change in the normal state which can be roughly calculated is by itself sufficient to account rather satisfactorily for the observed changes in the transition temperature The conclusion is therefore that the entropy-temperature curve for the superconductive state is not sensitively affected by the addition of small quantities of other metals in solid solution

The entropy of the normal state for low temperatures is given by

$$S_n = aT,$$

where a, apart from universal constants, depends only on the density of electron states in the metal at the boundary between occupied and unoccupied levels. This quantity is usually denoted in the literature[2] by $N(E_0)$ In the Sommerfeld free electron model, $N(E_0)$ varies as $n^{1/3}$, where n is the number of free electrons per unit volume. In an actual metal it is known that $N(E_0)$ is rather greater than the value given by the Sommerfeld model and in general increases rather more rapidly with n. For the superconductive state the entropy may be represented by

$$S_s = bT^x,$$

where x lies between 2 and 3 and is, in fact, in most cases very close to 2. The variation in the transition temperature T_c due to a variation of a with b remaining constant is given by

$$\frac{\delta a}{a} = \frac{x-1}{T_c}\delta T_c.$$

Using the Sommerfeld model for the normal state, we have therefore

$$\frac{\delta T_c}{\delta n} = \frac{1}{3(x-1)}\frac{T_c}{n}. \qquad (1)$$

In the case of an actual metal, the factor 1/3 is replaced by the number $(n/N(E)^2)\,(dN(E)/dE)_0$ which may differ from 1/3 by a factor of 2 or 3 It is more convenient to use the number of free electrons per atom, n_0, in place of n in equation (1), so that in a real metal n_0 will correspond to the valency and in a solid solution to the weighted average valency

Solute	Valency	$(dTc/dc)_0$ exp	dn/dc	$(dTc\,dc)$ calc (1)
Solvent metal lead, Tc - 7·26				
Hg	2	1·7	−2	−1·2
In	3	−0·8	1	0·6
Tl	3	4·1	1	−0·6
Bi	5	+7·1	+1	+0·6
Solvent metal thallium, Tc – 2·38				
Sn	4	+2·7	+1	+0·26
Pb	4	+5·5	+1	+0·26

EUTECTIC ALLOY OF TIN WITH THE FOLLOWING METALS (TRANSITION TEMPERATURE OF PURE TIN, 3·69° K)

Metal	Valency	Limit of solubility in tin	T_c
Bi	5	12% (atomic)	3·79°K
Zn	2	1% ,	3·66
Cd	2	10% ,	3·62

The accompanying table gives the available relevant experimental data[3] $(dT_c/dc)_{c-0}$ is the rate of change of the transition temperature with concentration of solute atoms, c, for zero concentration. This quantity can only be obtained roughly from the existing experiments. The fourth column gives the rate of change of electron concentration with concentration of solute atoms, and the fifth the values calculated from equation (1) Apart from changes in electron concentration, the entropy of the normal state is affected by changes in the lattice parameters arising in the formation of the solid solution, and this may in special cases be of importance

Agreement in order of magnitude between experimental values and those given by (1), and particularly the fact that the transition temperature varies in the same direction as the electron concentration, support the view that the change in transition temperature is brought about largely by the change in the normal state of the metal.

A Ponderomotive Effect associated with the Flow of Heat through Liquid Helium II

It has recently been suggested[1,2] that liquid helium II shows a certain similarity with a Knudsen gas, the atoms moving with a very long mean free path. From the formula

$$l = \frac{3\varkappa}{c_v \rho v}, \tag{1}$$

which is quite general (l is mean free path, $\varkappa$ is thermal conductivity, c_v is specific heat per gram, ρ is density, v is velocity of the atoms or quanta performing the heat conduction), one obtains values for l of several millimetres even if one takes for $\varkappa$ the smallest values measured by Keesom[3] and assumes for v either the velocity of sound or a value deduced from the zero point energy (both about $2\cdot5 \times 10^4$ cm./sec.). Thus, if a Knudsen manometer were immersed in helium II, the moving vane should be repelled from the heater plate with a force of the order of magnitude

$$f = Q/v, \tag{2}$$

where Q is the total heat flow striking the vane provided the separation of plate and vane is less than the mean free path. Expression (2) is also of a very general nature and can only be modified by a factor of the order of magnitude of unity arising from the velocity distribution and the type of the collisions of the atoms with the vane.

I have looked for a force of the order given by (2) using a modified Knudsen manometer. The heater (2 cm. × 2 cm.) consisted of a vertical electrically heated plate. The vane (1 cm. × 1 cm.) was suspended parallel to this at a distance of about 1 mm. The deflections of the vane could be observed on an immersed scale through the Dewar vessels from outside, and from the deflections f could be determined.

The results were quite unexpected. Up to a power dissipation of $1\cdot3 \times 10^{-2}$ watt/cm.^{2}, no repulsion of the vane was observed in the whole temperature range between 1·5° K. and the λ point, though at this rate of heat supply one fiftieth of the force given by (2) would have been easily detectable. The plate separation was between 0·8 and 1·0 mm.

On further increasing the supply of heat, the vane was actually attracted to the fixed plate. At the present stage it is only possible to give the order of magnitude of this effect. At about 2·1° K. with a power dissipation of 5×10^{-2} watt/cm.^{2}, the attraction amounted to about 6×10^{-2} dynes, with a plate separation of 1·0 mm. If the heat input was increased further still, the vane appeared to be held close to the heater for the whole temperature range between 1·6° K. and the λ point, provided that the original distance was less than 0·7 mm. However, if it was about 1·5 mm., repulsion was observed at lower temperatures.

It appears therefore that the phenomena are complex and need extended investigation, but that in any event they are not to be explained by the simple assumptions mentioned above. Nevertheless, even at this stage it seems profitable to put forward certain alternative speculations, as they not only suggest an explanation of the above phenomena but may also be helpful in the discussion of experiments of quite a different type.

The attraction and repulsion are both assumed to be due to a peculiar flow of liquid associated with the flow of heat. Though the possibility that this flow is merely set up by variations of density cannot be excluded, it seems more probable that the driving force is the same as in the 'helium fountain', where helium flows through capillaries from regions of lower to higher temperatures even against a pressure gradient[5]. Since this force must be exerted by the walls of the capillary, one can expect such a 'capillary flow' along any wall immersed in helium II along which a temperature gradient is maintained, while the return flow, obeying ordinary hydrodynamics, will take place at a greater distance from the wall.

As the heat resistance of the vane in the present experiment is comparatively high, there will be a radial temperature gradient along the heater, the highest temperature being in the middle of the heater opposite the vane. We might therefore expect a capillary flow towards the centre within a small layer near the heater, gradually changing into a hydrodynamic flow, which streams backwards within the rest of the interspace between plate and heater. In the case of streamlined flow, the latter would cause attraction arising from the Bernoulli force

$$p - p_0 = \tfrac{1}{2}\rho w^2 \tag{3}$$

while under the influence of turbulence the vane could be blown away.

Now the question arises whether perhaps this flow of liquid can account for the high values of heat conductivity observed in helium II. It has been pointed out by Allen and Misener[4] that ordinary heat convection is insufficient to explain them. However, the capillary flow must be associated with an appreciable flow of heat of quite a different character.

Suppose a quantity q of liquid flows per second against a pressure difference dp between two reservoirs at the temperatures T and $T + dT$ by the fountain mechanism. Then the work done per second is qdp, and according to the Second Law of Thermodynamics the capillary flow must be connected with a reversible heat flow

$$Q = Tq\frac{dp}{dT} \tag{4}$$

from $T + dT$ to T. This is in addition to any irreversible heat flow which might already exist if no liquid were flowing. In other words, the fountain effect is the exact mechanical analogue of the thermo-electric effect. Q corresponds to the Peltier heat, dp/dT to the thermo E.M.F. per degree, while the capillary flow and the hydrodynamic flow correspond to the electric current in two different metals.

No quantitative results for Q or dp/dT are available at present. If one assumes with Tisza[6] that the part of the liquid transferred by capillary flow has actually zero entropy, one obtains

$$Q = TS = Tq\rho s, \tag{5}$$

where $S = q\rho s$ is the entropy of q cm.^{3} of liquid helium at the temperature T.

If we apply (3) and (5) to the present experiment using the value of the attraction as given above, we obtain for the heat associated with the flow about 2×10^{-1} watt. The actual heat input was $0\cdot5 \times 10^{-1}$ watt, which is the same order of magnitude.

We cannot, however, at this stage, conclude definitely how far the capillary flow along walls can account for the high heat conductivity of helium II.

A satisfactory test of the above hypothesis would require experimental values for Q or for dp/dT, as well as a more detailed knowledge of the laws governing the flow of liquid helium II

Photographic Tracks from Cosmic Rays

WHILE examining some photographic plates which had been exposed to cosmic radiation, a peculiar grouping of tracks of very short range was observed, which may possibly be due to a novel effect

The plates were half tone Ilford plates ($70\,\mu$ thick) they were protected by a layer of glue free paper and then covered with layers of pure paraffin in varying thickness, from 1 mm to 15 mm The packets were exposed to cosmic rays at 3,400 metres altitude at the Institut fur Strahlungsforschung on Jungfraujoch I am glad to express here my gratitude to the Director and the assistants there for their kindness and help

After an exposure of five months the plates have now been developed and examined They present singular tracks and stars like those reported in previous papers[1], but besides these, many groups of very short tracks are seen for which no parallel has been observed in earlier experiments The number of individual tracks in one group was in general four to eight, certain groups showed up to twenty or thirty and a few were so dense that individual tracks could be distinguished only in the peripheral parts, while the inner parts were visible as black spots, even to the naked eye The range in air corresponding to the length of the tracks is of the order of 1 cm or less, the tracks diverge from closely situated points in the photographic emulsion, sometimes two tracks arising from one point The number of groups seems to increase with the thickness of the paraffin With lead as absorber, or without absorber, only very few groups with a small number of tracks have so far been found

The first question which arises is, whether the groups could be due to contamination from radioactive substances, either in the paper or in the paraffin This, however, seems not to be possible for two reasons (1) The tracks do not start from the surface of the emulsion, but at a certain distance below the surface—generally $8–10\,\mu$, groups with a limited number of tracks have also been observed at greater depths—even $30\,\mu$ below the surface Such an effect might be due to an accidental desensitization of the uppermost layer of the emulsion, say, by pressure from the paraffin, but such a desensitization can scarcely be admitted here because reduced silver grains are often found between the group of tracks and the surface (2) The very short range of the tracks, they could in fact only be due to heavy contamination with samarium, which is highly improbable, while it would also be necessary to admit that groups of samarium atoms had diffused below the surface of the emulsion Moreover, direct experiments with samarium as contaminating substance have never given a corresponding effect.

As a first tentative explanation it may be suggested that cosmic rays give rise in the paraffin to a secondary radiation, which in turn leads to disintegration processes of the atoms in the photographic emulsion The group tracks would then be due to slow moving disintegration particles

This is corroborated by the fact that inside the groups, between the tracks, silver grains, both single and double are observed much more frequently than outside, this reduction of silver of course would be due to the action of electrons, γ rays or heavy particles of very short range resulting from the disintegration process This and other alternative explanations will be discussed in a detailed report, when further observations have been collected

The examination of plates has been carried out in the Universitetets Kjemiske Institutt, Blindern pr Oslo, and I wish to express my sincerest gratitude to Prof Ellen Gleditsch for her kind hospitality that has made it possible for me to continue my investigation

Generation of Auroras by Means of Radio Waves

ABOUT a year ago, attention was directed to a new mathematical theory of radio interaction[1] which, contradicting the original mathematical theory[2], leads to the important conclusion that abnormally large impressed modulations may be caused by waves the frequencies of which are nearly equal to the local gyro frequency (that is, the frequency of gyration of a free electron in the earth s magnetic field) This conclusion was strikingly confirmed in the course of experiments[3] carried out in March 1937

It is therefore now appropriate to mention other deductions from the new theory which will be of general interest

Since a gyro wave (that is, one with frequency nearly the same as the local gyro frequency, $He/2\pi m$) can cause such notable effects in the E layer, it is natural to inquire about the details of a radiator of gyro waves which would be capable of generating a visible glow discharge in that layer

From the results of the experiments of H A Wilson[4] with discharge tubes containing air at low pressures and from generally accepted knowledge about the ionosphere and radio waves, it can be deduced that at night, in latitudes where the terrestrial magnetic field is approximately vertical, a visible glow discharge usually can be produced near the lower part of the E layer by means of a radio station which radiates an appropriate circularly polarized vertical beam of gyro waves at the rate of 500 kilowatts by means of an aerial system consisting of 800 horizontal half-wave aerials lying in a plane situated one quarter of a gyro wave length above the ground

This aerial system would have approximately the appearance of a square network with a side 2 kilometres long, a mesh of 100 metres and an elevation of 50 metres About half the beam would be contained mostly within a cone of vertical angle equal to 6°, and the resultant celestial glow discharge would lie below the height of 100 kilometres and be about fifty times as bright as the sky on a moonless night.

No great absorption of the beam by any ionized strata lower than the *E* layer need be anticipated, since the absorption of an extraordinary gyro wave is inversely proportional to the collision frequency and so diminishes very rapidly with the height; this is also indicated by the experiments[3] on radio interaction mentioned above By generating the gyro waves in a series of pulses, a corresponding series of glow discharges could be produced by means of a much less powerful station or with a much smaller aerial system than is indicated above

Such artificial auroras would be of great scientific value, as they would allow those parts of the atmosphere which lie nearly 90 km high to be studied by means of *controllable* spectroscopic and other observations It is therefore to be hoped that means may be found to use the 500-kilowatt broadcasting station at Cincinnati, or that at Moscow, to attempt to produce such auroras.

It can also be deduced that with an aerial array similar to, but much less extended than, that mentioned above, and with gyro waves radiated at the rate of about one million kilowatts, it is possible on clear nights to provide over an area of about 10,000 square kilometres the minimum illumination of 0·02 foot candles prescribed for roadways[5]; this illumination is approximately the same as that provided by the full moon when overhead Only a small fraction of the energy in the form of radio waves would be reflected down to the ground where it might otherwise disturb ordinary radio reception

The above conclusions are supported by the experiments of Mr. Gill[6], who found that the oscillating potential required to start a discharge in a bulb containing air at low pressure can be very much reduced by applying that magnetic field which causes electrons to gyrate with the same frequency as that of the starting potential

The details of the arguments which lead to these conclusions are in the course of publication in the *Philosophical Magazine*

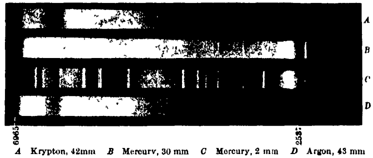
Spectral Continua of the Rare Gases

IT is known that most of the rare gases emit spectral continua under certain conditions of excitation. The most favourable conditions for excitation are obtained in the uniform positive column of an electric discharge using wide tubes, high pressures and low density currents. In the range of pressures, p, over which the continua predominate, the ratio of the axial force Z to the pressure p is small and decreases slowly with increase of pressure. As the pressure increases, the intensity of the continua emitted increases with respect to the intensity of the line spectra, and the intensity of the lines requiring the higher energies to excite them decreases rapidly with increase of pressure compared with that of the lines requiring the lower energies. For example, in argon and krypton at 40 mm pressure, the only lines with intensities comparable with that of the continuum are those which emanate from the $2p$ levels requiring about 13 electron volts to excite them

The accompanying photograph shows the spectra of the light emitted from the positive column in a tube 3 cm in diameter in argon, krypton and mercury, over the spectral range 7200 A -2200 A



A Krypton, 42mm *B* Mercury, 30 mm *C* Mercury, 2 mm *D* Argon, 43 mm

It will be seen that these gases have the same long-wave spectral limit at about 6850 A, which is about the value of the limit in helium That this long-wave limit is not due to lack of sensitivity of the photographic plate has been shown with long-range plates sensitive to 8800 A

The theory suggested for the well-known hydrogen continua, namely, that the radiation is emitted by an unstable molecule consisting of an excited and a neutral atom, appears to be suitable to the explanation of the phenomena in the rare gases It would explain the long-wave limit observed and would suggest a short-wave limit in the far ultra-violet corresponding to the energy of the excited state involved in the formation of the unstable molecule. It is interesting that the long-wave limit should be the same for helium, argon and krypton, and it is remarkable that mercury, in spite of essential differences, should also have a limit at nearly the same value

Correlations between Electronic States of Atoms and Molecules in the Alkali Earth Hydrides

IN a recent paper, More and Cornell[1] discuss the potential energy curves for strontium hydride (SrH) based on some absorption investigations of the *C* and *D* band systems of this hydride. Two years ago, in a similar investigation (not mentioned in the paper of More and Cornell), I obtained[2] somewhat different results concerning the correlation between the energy levels of SrH and Sr+H. More and Cornell suggest that the *C*, $^2\Sigma$ state of SrH predissociates into the ^1D level of Sr. Correspondingly, the *D*, $^2\Sigma$ and *E*, $^2\Pi$ are connected with ^3D, and the *A*, $^2\Pi$ and *B*, $^2\Sigma$ with the ^3P state of Sr In my previous work, on the contrary, I proposed the ^1P level of Sr as the predissociation limit of $C,{}^2\Sigma$, all remaining states A, B, D and E dissociating into ${}^2P$ This correlation of mine was suggested as an alternative in the paper of More and Cornell

It is convenient to undertake the correlation SrH – Sr+H in connexion with the similar process CaH – Ca+H, because the energy schemes in both cases are almost identical[2] Further, it must be regarded as most probable that the ground level (N) of the hydrides dissociates into ${}^1S$ and the A and B levels go to ${}^2P$ Accordingly, if the ${}^2P$ or ${}^2D$ levels of the atoms are taken as predissociation limit, two different dissociation values are obtained for the N, A and B states A comparison between these two sets of values and those which are obtained with the Rydberg extrapolation method, shows that the choice of ${}^2P$ as predissociation limit is much more probable than that of ${}^2D$ The same result has also been obtained by Humphreys and Fredrickson[3] although the dissociation values given by them are not correct It is easy to see that the Birge Sponer extrapolation in these cases gives by no means correct dissociation values, because the Birge Sponer values are about 5 000 cm $^{-1}$ higher than the highest possible dissociation values in the N, A and B states of CaH and SrH

A fuller account of these problems will appear in the *Zeitschrift fur Physik*

Kramers' Law A Correction

IN a recent letter[1] it was shown that the number of arrivals, p_n, in the n^{th} quantum state of the hydrogen atom in a discharge tube and in the planetary nebulæ was not the same as the number of captures predicted by Kramers Law The arrivals, p_n, were computed from measured line intensities for $n \geqq 3$, and the number of captures on $n = 2$ was obtained directly from the Balmer continuous emission, Ba_c If, as convincing arguments[2] appeared to show, these observed arrivals, p_n, were almost wholly due to captures of free electrons, it followed that Kramers Law was wrong This view was strengthened in the case of the discharge tube by a measurement of the Paschen continuous emission, Pa_c, which gave directly the number of captures on $n = 3$, and which was thought to be of the same magnitude as p_3

The infra red measurements of the Pa_c have recently been repeated with greater accuracy and a numerical error found in the earlier measure It now appears that the ratio of Pa_c to Ba_c is very closely that predicted by Kramers Law, namely, 0 06[3], therefore the law is correct for hydrogen, as expected theoretically It is evident, then, that p_3 is one thousand times greater than the number of captures on $n = 3$ both in the electrodeless ring discharge and in the nebulæ, in other words, excitations to the third quantum level are about one thousand times as frequent as captures of free electrons there This fact will necessitate a revision of the prevailing theory of nebular emission

Thus though Kramers' Law should not be used in calculating the absorption of the alkalis and the non hydrogenic elements in a stellar atmosphere, these revised and extended measurements indicate the validity of the law for atomic hydrogen

The Rotating Pendulum and the State of Adaptation of the Eye

THE experiments of Lythgoe[1] on the rotating pendulum show that the latent period of the eye is not *directly related to the brightness perception* of a viewed object The latent period seems to be more closely related to the sensitivity of the eye with higher sensitivity it is mostly longer, with lower sensitivity shorter Lythgoe was led to assume that nervous interaction tends to shorten the latent period Crawford[2] states that the effect is almost entirely in accord with the hypothesis that the latent period varies in the same sense as the concentration of photochemical substance in the retina, and concludes that the effect might therefore provide a simple measure of the concentration of photochemical substance in the retina

Experiments on the change of sensitivity of the fovea under influence of a glaring light source placed somewhere else in the field of view point strongly against Crawford's and in favour of Lythgoe's hypothesis

It can be shown by means of a binocular method[3] [4] that the presence of a glare source in the field of view causes the sensitivity of the fovea to drop to a much lower level within 0 1 second (α adaptation) If the sensitivity were determined solely by the concentration of a photochemical substance, α adaptation ought to be due either to the stray light within the eye or to a diffusion of photochemical substances over the retina It can be proved, by measurements on diascleral re illumination, that α adaptation is not due to this stray light, but to an influence originating in the strongly illuminated part of the retina By measurements on the velocity of α adaptation over the retina, a value was obtained which is far too great to be accounted for by processes of diffusion

α Adaptation might be of a purely electrical nature, due to the leakage currents which are known to be produced within the eye when a point of the retina is illuminated Although this hypothesis qualitatively accounts for many of the observed characteristics of α adaptation, it cannot account for all of them, especially those with coloured light After excluding the possible explanations of purely physical or chemical nature, we are thus left with only one possibility to account for α adaptation an inhibitive influence transmitted by the retinal synapses from the illuminated area of the retina towards the fovea

Against Crawford's assumption also is the fact that for the one form of adaptation for which photochemical changes seem definitely responsible, namely, prolonged dark adaptation, no rotating effect occurs This alone would already suggest that the effect of varying latent period is due to an entirely different mechanism

Apart from any speculations as to its exact mechanism, the Lythgoe effect is of special importance to visiodynamics because it illustrates once more that the retina is the seat of processes which manifest themselves only indirectly in the ultimate brightness perception

Efficient Vacuum Fractionating Columns

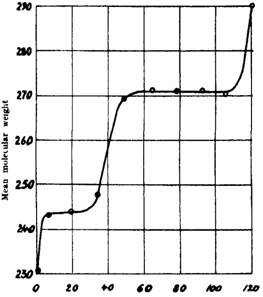
THREE vacuum distillation apparatuses capable of distilling amounts from 5 gm to 500 gm have been constructed for preparative and analytical work particularly in regard to fatty acid esters They are also efficient for other higher boiling mixtures, such as hydrocarbons, alcohols, amino acid esters and dicarbonic acid esters The apparatuses are based *inter alia*, on the experience of Dr Podbielniak in connexion with vacuum fractionation In the choice of material and construction, particular attention has been given to the question of securing an effective apparatus at a reasonable outlay

The apparatuses are equipped with an electrically heated flask, column and column top, each of which can be regulated independently of the other The temperature is controlled by thermocouples with an accuracy of ±0 5° C The columns are fitted internally with spirals of monel metal or stainless steel and are furnished with a high vacuum jacket of Durandl glass fused to the column On the outside, the columns are insulated with asbestos fitted with mica windows The electric heating spiral is wound round a glass tube outside the vacuum jacket Further details concerning the apparatus will be published later

With the aid of the smallest apparatus, a mixture of 9 71 gm palmitic acid methyl ester (iodine value 0 25) and 8 7 gm refractionated C_{18} ester mixture (iodine value 72 3) including oleic, stearic, and eladic acid methyl esters was fractionated The following table illustrates the effectiveness of the fractionation

Fraction No	Ester (gm)	Per cent distilled	Saponification equivalent	Iodine value	Per cent C_{18} ester
1	1 015	5 5	—	0 69	0 3–0 5
2	1 722	14 9	268 8 ±1	0 46	
3	1 416	22 6		0 37	
4	2 389	35 6		0 56	
5	1 518	43 8		0 94	0 9
6	1 131	49 9	—	3 31	4 1
7	0 556	52 9		31 6	41 9
8	1 108	58 9	294 2 ±1	73 2	93 95
9	1 353	66 3	296 5 ±1	74 3	98 100
10	3 761	86 7	296 7 ±1	71 9	98 100
11	1 731	96 1	295 6 ±1	63 8	98 100

The table shows that 83 per cent of the palmitic acid ester recovered has a degree of purity of 99–99 7 per cent Owing to the less accurate method of analysis employed for determining saponification values, the purity of the recovered C_{18} ester fractions could not be determined more accurately than to between 98 and 100 per cent Of the total C_{18} ester, 79 per cent of this degree of purity has been recovered The intermediate fractions, that is to say, ester mixtures of a purity less than 98 per cent, amounted in all to 16 per cent of the total amount distilled The distillation residue was 0 71 gm, that is, 3 9 per cent



Fatty acid methyl ester distilled (gm)

The iodine values show that an accumulation of stearic acid ester has occurred especially in the case of the last fraction (25 5 per cent as compared with 13 per cent for fraction 9 in other words, an accumulation of almost double This also manifested itself in the fact that fraction 11 was solid while fraction 9 was liquid)

As the graph shows, satisfactory results were also attained with apparatus intended for larger quantities An approximately accurate idea of the ester mixture components is obtained from the distillation temperature diagram

Interfacial Tension between Mercury and Water

THE interfacial tension between mercury and water is generally accepted, on the basis of capillary rise and drop weight measurements, as being about 375 dynes/cm at 20° C [1], but using a sessile drop method, Burdon and Oliphant[2] have obtained a value of 427 dynes/cm The suggestion that the discrepancy might be due to the invalidity of certain assumptions made in the calculations from capillary rise and drop weight observations was disposed of by Brown[3], who obtained a value of 374 2 dynes/cm at 25° C by the sessile drop method

During experiments on the electrocapillary curve of water, using a sessile drop as polarized electrode, it has been found possible to obtain at will either of the above values for the unpolarized interface according to whether oxygen is or is not rigidly excluded from the water, the lower value is obtained in the presence of air, the higher value when oxygen is excluded Confirmatory determinations have been made by the capillary rise method, using the apparatus of Bartell, Case and Brown, suitably modified Working *in vacuo*, the figure obtained was 426 dynes/cm, and in equilibrium with either hydrogen or nitrogen at a pressure of one atmosphere, 427 dynes/cm, the temperature being 20° C When air is admitted the value falls, and there are indications that the tension of a freshly exposed interface may have any value between 375 and 427 dynes/cm according to the oxygen pressure over the system

It is significant that the higher value found for the unpolarized surface is identical with that found by Gouy[4], with cathodic polarization, at the maximum of the electrocapillary curve of pure water This suggested that the effect of excluding oxygen consists simply in a lateral shift of the electrocapillary curve along the axis of polarization This was confirmed by plotting the cathodic branch of the curve (the only one accessible to measurement under oxygen free conditions) in the same apparatus under normal and under oxygen free conditions In the latter circumstances, the maximum of the curve was in fact found to lie slightly on the anodic side of zero polarization It seems reasonable to suppose that the effect of dissolved oxygen is to produce mercury ions which are strongly adsorbed at the interface and produce a lateral displacement of the cathodic branch of the electrocapillary curve in the same way as the so called capillary active ions

Dependence upon State of the Dielectric Polarizations of Ammonia and its Three Methylated Derivatives

NEW measurements recently completed enable us to provide for the first time a set of data to show the dependence upon state of the dielectric polarizations of ammonia (NH_3), methylamine ($MeNH_2$), dimethylamine (Me_2NH), and trimethylamine (Me_3N) The essential results are tabulated below and illustrate the influence of the medium in dipole moment determinations[1] The figures represent the total polarizations of these four substances calculated at 25° by the usual formulæ

POLARISATIONS OF AMMONIA AND ITS METHYL DERIVATIVES

State	NH_3	$MeNH_2$	Me_2NH	Me_3N
Gaseous at zero pressure	49 6	44 9	36 6	28 6
Dissolved in benzene at infinite dilution	46 5[2]	55 4	50 3	35 2
Liquid	23 8[3]	34 9	41 3	30 5

Full details of this work, and a discussion of its implications, will be published elsewhere later For the present the relative magnitudes of the ratios $P_{\text{gaseous}}/P_{\text{dissolved}}$ and $P_{\text{gaseous}}/P_{\text{Liquid}}$ may be noted It will be seen that while ammonia conforms to the more common type of behaviour and has both these ratios greater than unity, the reverse is the case for the di and tri methylamines, where the differences between the polarizations are greater than in other previously noted[4] examples of this kind of abnormal[5] solvent effect

The Polarographic Sero-Reaction for Cancer

IN a detailed communication[1] I have described two polarographic sero reactions concerning typical changes in human serum of individuals suffering from cancer sarcoma acute inflammations fever or some bile and liver disorders

A re investigation of the reaction I use has given rise to some erroneous remarks Messrs F Bergh O M Henriques and C G Wolffbrandt state in a letter in NATURE[2] that the great effect in the polarographic sero reaction cannot be due to the presence of cystine compounds as the concentration of cystine had to be 100–1000 times greater than that generally found in serum These investigators however, have wrongly used a solution of cobaltamine (reagent for protein containing cystine) instead of the reagent for pure cystine which is cobaltous chloride (divalent salt) When the latter proper reagent is used a 1000 times smaller concentration of cystine causes the same effect as is shown in the last curve of these authors and is in complete agreement with the cystine content generally found in serum (Their effect is obviously due to a trace of divalent cobalt in the trivalent salt solution used brought in by the reduction with cysteine)

As a result of this mistaken experiment, Messrs Bergh Henriques and Wolffbrandt ascribe the polarographic effect in the cancer reactions to an additive expression of several substances In answer to this suggestion it should be emphasized that only such substances can be considered which cause the typical polarographic effect in the buffered cobalt solution and give an empty curve in the absence of the cobalt reagent This is the chief characteristic of the polarographic double wave produced by proteins containing cystine or by their degradation products Therefore none of the chemically defined substances investigated by Messrs Bergh, Henriques and Wolffbrandt can be taken into consideration except cystine or cysteine

These authors also show that urine and water extract of yeast give in cobaltic solutions similar curves to the deproteinated serum This is in accordance with facts already established[3] as well as with my interpretation of them, that the polarographic effect is to be ascribed to proteins or polypeptides containing cystine nuclei present in these biological fluids Their finding that the substance responsible for the polarographic effect in urine passes slowly a Cellophane' membrane clearly indicates that the proteic substance in urine has a smaller molecule than that in the deproteinated serum

To the discussion of the view of Waldschmidt Leitz that the polarographically active substance in carcinomatic deproteinated serum may be a sulphur free mucoid[4] I would point out that this assumption is not in accord with my experimental facts, the hydrolysates of the deproteinated serum solutions in question show clearly the presence of cystine and moreover, in the same relative content as found in the various non hydrolysed deproteinated pathological or normal sera the cystine content in the deproteinated serum is of the order of 10^{-4} molar and is always higher in the carcinomatic case, against the necessity for a mucoid theory is also the fact that an identical polarographic effect is evoked by a deproteinated solution of pure crystalline albumin, if the albumin is first degradated with the alkali or pepsin[5]

The experimental evidence thus shows convincingly that the changes in pathological sera polarographically detected consist in a proteolytic degradation of serum proteins by which cystine containing high molecular products bearing the character of albumose, are split off The origin of this proteolysis taking place in the blood must be sought in the increase of some products of the pathological metabolism, of the type of Abderhalden s proteolytic reactions

Photo-ammonification of Organic Nitrogenous Compounds in the Soil

IN recent years Gopala Rao and Dhar[1] Gopala Rao[2] Dhar and co workers[3] and Corbet[4] have shown that nitrification in soils occurs partly as a photochemical reaction under the influence of sunlight Dhar and co workers[5] have also brought forward considerable evidence to show that fixation of atmospheric nitrogen is favoured by sunlight

We have now found that the decomposition of various nitrogenous compounds, the so called ammonification occurs as a purely photochemical reaction in the presence of photocatalysts like heated soil or ignited ferric oxide Aqueous solutions of various nitrogenous compounds were exposed to sunlight (for 30 hours) in 'Pyrex glass flasks under sterile conditions The amount of ammonia liberated in the decomposition process is estimated by Folin s method The results are as given below

	Milligrams of ammoniacal nitrogen per litre	
	Ferric oxide as photocatalyst	Heated red soil as photocatalyst
M/20 glycine	43 75	13 85
alanine	61 25	14 00
aspartic acid	65 65	17 30
glutamic acid	8 75	7 00
urea	28 00	12 72

It thus appears that many important chemical reactions in the soil can be brought about by the photochemical action of sunlight, independently of bacteria

Further work is in progress

Effect of Pyridine Compounds on the Nutrition of *Staphylococcus aureus*

RECENT investigations have established the necessity of nicotinic acid (or amide) for the growth of *Staphylococcus aureus*[1] In a previous report it was shown that the ability of this organism to utilize compounds related to nicotinic acid is limited We have since prepared several compounds of interest in this connexion, and the determination of their biological activity is herewith reported

The synthetic amino acid glucose medium of Fildes *et al*[2] was employed in testing the activity of the series of compounds The compounds were tested in the presence of an excess of thiamine (0 05 gamma per 10 c c of medium) using an 18 hour culture of *S aureus*

Nicotinyl glycine exhibited growth promoting activity in the same order of concentration as nicotinic acid Trigonelline, pyridine betaine β-carboxylic acid, α amino pyridine, and α amino pyridine β carboxylic acid were completely inactive as growth factors for *S aureus* It may be of interest to recall that Ackermann[3] isolated nicotinyl glycine and trigonelline from urine following the administration of nicotinic acid

A *Saccharum* - *Zea* Cross

BOTH *Saccharum* and *Zea* are distinguished by the readiness with which they cross with related genera For example, while Mangelsdorf and Reeves[1] have crossed *Zea Mays* with *Euchlæna* and *Tripsacum*, Venkatraman and Thomas[2] have crossed *S officinarum* with a species of *Sorghum* and even the remotely related *Bambusa*[3] I have also crossed *S officinarum* with *Imperata Cylindrica* Beaew and *S spontaneum* L with *Sorghum Durra* and *Sorghum halepense* In spite of *Zea* and *Saccharum* being in two different sections of the Gramineæ—Andropogoneæ and Maydeæ (Bews)—I thought it worth while to cross them and after several attempts using many thousands of flowers of a male sterile variety (Vellai) of *S officinarum* $2n = 80 = 8x$ as the female parent, and variety

Golden Beauty of *Zea Mays* $2n = 20$, $2B$ as the male parent, I obtained a single seedling This plant has received the expected 40 chromosomes from the *Saccharum* parent and 12 chromosomes from the male parent *Zea* Amongst these the VI nucleolar chromosome of *Zea Mays* is recognizable

PHOTOMICROGRAPH OF THE CHROMOSOME COMPLEX OF THE HYBRID BETWEEN *S officinarum* (VELLAI) AND *Zea Mays* (GOLDEN BEAUTY) SHOWING THE SINGLE VI NUCLEOLAR CHROMOSOME AND THE *B* CHROMOSOMES RECEIVED FROM THE MAIZE PARENT

The hybrid resembles the *Saccharum* parent more closely as we should expect from these chromosome contributions but it has the characteristic epidermal hair found on the upper side of the leaf in *Zea Mays* and related genera The cross however is dwarf in habit and although it has tillered freely has not produced flowering canes after twenty two months It lacks the vigour and early maturity found in *Saccharum Sorghum* hybrids

This cannot be due simply to the remoteness of the cross since the *Saccharum Bambusa* hybrids are very vigorous It must rather be due to the inequality of the contribution of the polyploid and diploid parents The same consideration is likely to vitiate the fertility of the hybrid The occurrence of these remote crosses in experiments indicates that the degree of anastomosis in the ancestry of polyploid species may be much greater than is commonly suspected

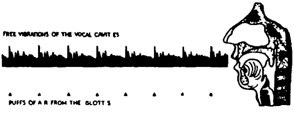
Vowel Vibrations and Vowel Production

THE dark band in Fig 1 is the reproduction of the speech track of a vowel (*a* in *hatch*) on a sound film The serrated upper edge is the registration of the vibratory movement of the particles of air, that is, it is the curve of vibration It is seen to consist of a series of portions—vibratory 'bits'—each of which begins strong and fades away to zero Such a curve is the registration of a free vibration aroused by an impulse that is not a vibration The glottal action consists of the repeated opening and shutting of the glottal slit A puff of air is sent into the vocal cavity at each opening movement, each puff sets the air in the cavity into vibration



FREE VIBRATIONS OF THE VOCAL CAVITIES
PUFFS OF AIR FROM THE GLOTTIS

Fig 1

The profiles in the vibratory bits are different for the different vowels (Fig 2) The vocal cavity therefore has a different form in each case The progressive change in the profiles of a vowel indicates that the vocal cavity changes its form constantly

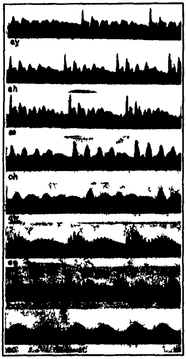


Fig 2

Every element in a vibratory bit has its characteristic rate of fading (logarithmic decrement) This is always large and never zero Forced—or resonance—vibrations do not fade, their logarithmic decrement is zero The vowel vibrations are as the tracks show, not forced vibrations, they cannot have been produced by resonance

Science and Mankind

IF we are to deal with the science of man, one of the first steps is to know our own position in the recurring cycles of civilization Then we can see in what direction we are heading at present

The cycle of economy and waste covers about 130 years The waste began at 1535, 1660 1790 1920 The more austere periods revived in 1560 1690 1820 , may we therefore look to 1950 or thereabouts ? This is known in the northern saying, from clogs to clogs in three generations

The long general cycle of civilization in Egypt bore the best work in 3700, 2600, 1550, 450 B C , and A D 760 an average of 1 115 years, resembling the 1,100 years of the Great Year" known to the Etruscans In each of the repetitions there was the same order of development—sculpture and architecture, painting, literature, mechanics, science, and lastly wealth, the stage we seem now to have reached Following that other races break in for plunder, and after some centuries of mixture a new dominant rises with a fresh cycle

A still larger cycle is that of race The Sumerian, the Semite, and the Perso Aryan have successively been leaders of the East We seem now to be nearing the end of Aryan rule, unless we can make recovery

FLINDERS PETRIE

Jerusalem

Points from Foregoing Letters

THE transition temperatures of superconductive alloys are considered by Dr H Jones who states that the change in the transition temperatures of superconductors when small quantities of other metals are added in solid solution arises from the change of entropy in the normal phase of the metal , the entropy of the superconductive phase being relatively little affected by the impurities

Dr H London has investigated liquid helium II by means of an immersed Knudsen manometer Instead of the repulsion which might be expected he found an attraction which seems to indicate that the heat flow is associated with a flow of liquid

Clusters of short range tracks observed on photographic plates covered with paper and paraffin wax and exposed for five months at an altitude of 3,400 m are described by Marietta Blau, who suggests that they are due to slow moving ionizing particles arising from the disintegration of atoms in the photographic emulsion This disintegration may be due to secondary radiation liberated in the paraffin wax by the cosmic rays

The possibility of generating artificial auroras by powerful radio stations such as those of Cincinnati and Moscow is discussed by Prof V A Bailey A visible glow discharge near the lower part of the *E* layer of the upper atmosphere could be produced by radiating a circularly polarized vertical beam of gyro waves at the rate of 500 kilowatts from a net work antenna of 2 km square With one million kw it might be possible on clear nights to provide an illumination over ten thousand square miles equivalent of that to the full moon when overhead

Photographs of the spectra of the light emitted from the positive column in an electric discharge in wide tubes (3 cm diameter) filled with rare gases (krypton, argon) or mercury gas are submitted by Dr S P McCallum They show that all have the same long wave spectral limit at about 6850 A

Renewed and extended measurements of the Paschen continuous emission of hydrogen leads Dr T L Page to admit that Kramers' law is valid for atomic hydrogen He still considers, however, that it should not be used in calculating the absorption of the alkalis and the non hydrogenic elements in a stellar atmosphere

Dr J F Schouten points out, contrary to Crawford's assumption, that the Lythgoe effect cannot be explained by theories based on photochemical changes alone The close resemblance between the varying latent period and the α-adaptation strongly supports Lythgoe s assumption that the effect is due to nervous interaction, which, moreover, must be of the inhibitive kind

The discrepancy in the recorded values for the interfacial tension between mercury and water, which vary from 375 to 427 dynes/cm , are due according to D C Henry and J Jackson to the effect of dissolved oxygen , this produces mercury ions which are strongly adsorbed at the interface In vacuum or in the presence of hydrogen or nitrogen the higher value of 426–427 dynes/cm is observed

The dielectric polarizations of ammonia and the three methylamines have been compared at 25° in the gaseous, dissolved (benzene) and liquid conditions by Dr R J W Le Fèvre and P Russell For ammonia the polarization is greatest as a gas and least as a liquid, but for di and tri methylamines the reverse is the case The last named amines are therefore good examples of a less common type of behaviour referred to previously by Dr Le Fèvre

Dr R Brdička criticizes the findings of F Bergh O M Henriques and C G Wolffbrandt concerning the probable substances responsible for the polarographic curve obtained with the serum of cancer patients He concludes that the only active substances are cysteine or cystine, arising from the break up of serum proteins (for example, albumose)

Liberation of ammonia from nitrogenous organic compounds by ignited ferric oxide and heated red soil under the influence of light, has been observed by G Gopala Rao and Ch I Varadanam The authors suggest that nitrification in soils may likewise be due to photochemical action

Nicotinyl glycine alone among a number of related compounds is found by Maurice Landy to possess the same growth promoting action upon *Staphylococcus aureus* as nicotinic acid

A photomicrograph of the chromosome complex in a hybrid between the sugar cane and the Indian corn is submitted by Dr E K Janaki Ammal, showing that a majority of the chromosomes come from the female sugar cane parent The cross is a dwarf plant resembling a sugar cane but having the characteristic epidermal hair found on the upper side of the leaf in *Zea Mays*

Photographs of profiles of vowel sounds on sound films are submitted by Prof E W Scripture He points out that every element in a vibratory bit has its characteristic rate of fading and that the vowel vibrations are not forced vibrations and cannot have been produced by resonance

Research Items

Piltdown Man a Re-examination

THE reconstruction of the skull of Piltdown man has been reconsidered by Sir Arthur Keith in the light of later discoveries, and his results were communicated to Section H (Anthropology) at the Cambridge meeting of the British Association He dwelt in particular on the anatomical resemblances between the Piltdown skull and the later Swanscombe skull Ape like features in the Piltdown bones and brain have escaped notice hitherto Piltdown man's forehead is strongly made, but upright, compared with his contemporaries in Java, China and Africa His head was high vaulted and his brain relatively large Yet in some parts of his face, particularly in the region of the chin and jaw, Piltdown man was the most ape-like of all He blended in the strangest and most unexpected manner characters of ancient ape and evolved man Apparently his progeny became extinct before the dawn of modern conditions Swanscombe man and the 'Lady of Lloyds' seem to be some of his remote descendants The greatest difficulty that the anthropologist has to overcome before he can interpret the Piltdown fossil fragments aright is due to an unexpected feature—the brain of Piltdown man, though moderate in volume and simple in convolutionary pattern, is asymmetrical to a degree rarely met with even in modern heads, although it has been believed that asymmetry is a mark of a highly evolved brain, and confined to modern races of man In the previous reconstruction of the Piltdown skull symmetry had been sought—in error In Swanscombe man there is also a high degree of asymmetry We have therefore to alter our conception of the antiquity and meaning of asymmetry Another unexpected feature is that ape like characters have been replaced by infantile This tendency to pedomorphism appears also in the Bushman, one of the most primitive of modern types

Occupational Risks

IN a paper before the Royal Statistical Society on May 17 last, Dr Percy Stocks, of the General Register Office, discussed the occupational risks of workers in different industries and in different localities of England and Wales He dealt in particular with the attempt to separate the direct effects of a man's daily work from the accompanying indirect effects of the environment in which, generally by compulsion rather than by choice, he lives in order to carry out that work In 1851, 1861 and in 1871, the Registrar-General tabulated the details of men in numerous occupations in different regions of the country, but little use was made of this material Dr Stocks cited examples of certain occupations which have given the statistical impression of being intrinsically unhealthy, as with the high cancer rate in 1930–32 amongst workers in slate, or the 17 per cent excess mortality for Lancashire coalminers over Nottingham and Derby miners in 1930–32, which owe their unfavourable mortality rates to their localization in counties whereby the workers and their families share higher death-rates In 1911–14, London's mortality was 8 per cent above and the average mortality of the neighbouring rural areas was 27 per cent below the rural rate London s excess above the neighbouring rural areas being 48 per cent In 1931 34 this was reduced to 32 per cent The inland towns with more than half their males at work in manufacturing industries, or mining and the northern textile towns, had a standardized mortality in 1911–14 between 35 and 40 per cent above that of the neighbouring rural areas an excess which in 1931 34 was reduced to 25 30 per cent The harmful effects of the older manufacturing industries upon the health of the towns in which they are located appears to have diminished during the last twenty five years, but is still considerable The Registrar General s review for 1934 associated the mortality of residents in the large towns with three factors overcrowding as measured by persons per room , the proportion of partly skilled or unskilled workers in the population , and the latitude, the mortality increasing in the more northerly towns especially among men of the unskilled class and their wives, but not among men of the professional class although present in their wives With rural workers the effect of "northernliness" on men's mortality is slight and is entirely absent in the unskilled class

Phytoplankton of the Thames

A COMPREHENSIVE study of the phytoplankton of the River Thames made by C H Rice during the period 1928–32 has recently been published in two papers (*Ann Bot*, New Series 2, No 7, 539–582, July 1938) In the first paper, the author, after a brief historical review, discusses the chemical and meteorological data such as air and water temperatures, sunshine, rainfall, natural flow of the river, chemical analyses Then follows the author's researches on the phytoplankton of the main river Here are assembled such important data as amount of phytoplankton, relation between its quantity and the environmental factors, composition and periodicity of the phytoplankton, with a list of constituent algæ The phytoplankton consists, as in other rivers, chiefly of diatoms, and monthly maxima of different genera are given Green algæ began to be prominent in mid summer Sunshine and flood rainfall (with its effect on velocity) are shown to be responsible for differences in composition and amount of plankton Further detailed observations on the phytoplankton of the main river are given in the second paper Here are considered periodicity of diatoms, Chlorophyceæ and Chrysophyceæ, and factors affecting periodicity The plankton of the tributary streams and backwaters is then described Evidence is brought forward to show that the plankton of the main river is not derived from that of the tributaries and backwaters, but rather from the bed in the shallow parts of the river

Ash Content of Apple Shoots

V G VAIDYA (*J Pom and Hort Sci*, 16, 101, 1938) has investigated the seasonal cycles of ash constituents in the terminal shoots of 15 year-old Lane's Prince Albert apples growing on Malling stocks II, V, VII, IX and B, in an attempt to find a relation between stock influence and nutrition Well defined seasonal cycles of lime magnesia potash and phosphoric acid were recorded These were similar for all the stocks except *M* IX which showed earlier cycles for total ash and P_2O_5 in the bark Trees on *M* IX alone showed a high percentage of lime and a low percentage of potash in the shoots compared with those on the other stocks P_2O_5 showed a negative and MgO a positive correlation with the known vigour of the stocks and MgO was negatively correlated with precocity the values for *M* IX and *M* VII being particularly low Particular attention is given to the bark/wood ratios of ash constituents and in this respect trees on *M* IX are outstanding the ratio for phosphoric acid being highest and for ash lime magnesia and potash lowest compared with the other stocks The bark/wood ratios are shown to be related to vigour those for ash and magnesia being positively correlated and for P_2O_5 negatively correlated, with tree height

Quadrivalent Nitrogen

The number of known free radicals of the type of diphenyl nitrogen oxide containing quadrivalent nitrogen is at present extremely small W Hucke and W Liegel have recently described the preparation of phenyl 9 *trans* decalyl nitrogen oxide (*Ber deutsch chem Gesells* July) The discovery of this substance resulted from an investigation of the properties of 9 nitroso *trans* decalin which was found to differ from aromatic nitroso compounds through its inability to form azo or azoxy compounds by condensation with primary amines or phenyl hydroxylamine On the other hand it reacts easily with phenyl magnesium bromide to produce phenyl *tert* decalyl hydroxylamine a colourless compound which oxidizes slowly on exposure to the air to form phenyl 9 *trans* decalyl nitrogen oxide (C_6H_5 NO $C_{10}H_{17}$) a stable red substance the molecule of which contains quadrivalent nitrogen and from which phenyl 9 *trans* decalylamine can be obtained by reduction This reaction appears to be peculiar to the aromatic series since the reaction between 9 nitroso *trans* decalin and alkyl magnesium halides results only in the formation of hydroxylamino decalin

Statistical Methods in Engineering Specifications

In a paper entitled A Statistical Examination of Specifications for the Mechanical Testing of Line Insulators by W T O Dea (*J Inst Elec Eng* **83** No 501 September) the probabilities involved in certain clauses of a Central Electricity Board specification are analysed mathematically It is shown that a batch of 2 700 units stands an even chance of acceptance as the result of testing a sample of 18 for guaranteed minimum strength despite the fact that there may actually be 130 defective units in the batch Such an accepted batch is made up into strings of *nine* in which case 35 per cent of single strings or 55 per cent of double strings may be expected to contain at least one defective unit It is suggested that better results might be obtained by the application of one of the statistical methods described in Dr E S Pearson s Statistical Methods in Standardisation (*B S S* 600, 1935) The author also suggests that although there is so much latitude in the applicability of present specifications, their clauses may have forced manufacturers to produce designs in which the quality of resistance to thermal stresses is unjustifiably impaired Statistical methods of appraisement might be expected to restore any such lack of balance in design and also to discount substantially the effects of possible prior testing by manufacturers, which may at present invalidate the conclusions reached by an inspector The paper concludes with appendixes which illustrate the necessity of choosing an adequately large sample a matter upon which existing specifications are commonly in error

Variation of Cosmic Rays with Time

The absence of any marked variation of the intensity of the cosmic rays with the position of the Milky Way in the heavens has been thought to exclude the generation of the radiation within our galaxy H Alfvén (*Phys Rev* **54** 97) shows that the paths of the particles are probably greatly complicated by electric and magnetic fields in interstellar space The east–west asymmetry of the cosmic rays shows that there is an excess of positively charged cosmic ray particles The resulting interstellar space charge will be neutralized by slowly moving ions which should follow the motion of the stars If the cosmic ray particles are not isotropic relative to the stellar system—for example if they have no share in the galactic rotation as formerly suggested by Compton and Getting—the relative motion of fast and slow particles leads to the existence of large magnetic fields in space With even a small anisotropy the fields would bend cosmic ray paths in curves of radii small compared with interstellar distances A high degree of isotropy of the radiation is therefore a consequence of the charge on the particles and tells us nothing about the place of origin of the rays

Physical Changes on the Moon

Mr Robert Barker has a paper with this title (*J Brit Astro Assoc* **48** 9 July 1938) in which he records the results of observations by himself and others on certain lunar features alleged to show physical changes Thus, two of the southern bands radiating from Aristarchus have very variable extensions and these could be best described as due to lowly vegetation subject to fluctuating harvests A mound between Cassini and the Great Alpine Valley shows considerable changes during each lunation and Emley supports Pickering s view that this phenomenon is due to hoar frost Mr Barker claims to have mapped a number of new craterlets in the south west area of Mare Crisium and several other lunar observers have corroborated his discovery He suggests that they escaped detection for a long time because they are the source of obscuring matter Amongst other changes noticed reference may be made to those on the west wall of Plato and the variations in depth of colouring and area were also recorded by Mr W E Fox Newark Mr Barker describes the changes as those that could be produced by quick growing vegetation which has about 15 days in which to complete a cycle of germination growth and fructification Mr T L MacDonald contributes some notes on the paper, and as director of the Lunar Section of the British Astronomical Association he is cautious before committing himself to acceptance of vegetation on the moon Varying libration or changes in the heating of the lunar surface may, he suggests be responsible for alterations in colour effect Further observations by independent observers and the investigation of the correlation of the effect with libration and other factors are most essential for progress in this branch

Three Meteoritic Falls in the U S.S.R.*

STONY METEORITE OF KAINSAZ

A FALL of meteoritic stones took place on September 13 1937, at 11 15 U T near the Kainsaz collective farm (Muslium Tartar Republic) 55° 26 N and 53° 15 E

A fire ball (bolide) with a short fiery train was seen moving in a north west direction leaving behind a smoky trail persisting for 10–15 minutes , in the air the fire ball was divided into parts The detonation was heard at a distance of 130 km

The fragments of a stony meteorite were scattered over the surface of an ellipse stretching in a north westerly direction with the axes 40 km and 7 km long

The largest very well preserved fragment weighing about 102 5 kgm fell at Kainsaz the extreme north west point of the ellipse and the smallest nut sized fragment at the opposite point of the ellipse near the village of Kostcievo Between these two points a number of smaller fragments were found weighing 53 kgm (Kainsaz) 27 5 kgm (Tash Flga) 22 kgm (Krasny Yar) and others a total of fifteen fragments with the total weight of more than 200 kgm have been found

The depressions caused by the largest fragments had the appearance of small pits with the depth approximately equal with one exception to the vertical dimension of the fragment

The fragments found were a dark grey colour with a greenish hue inside had chondrules and were covered with a black somewhat rough crust with characteristic piezoglypts These specimens affected a magnetic needle slightly The meteorite has been provisionally referred to the chondrites

I S SELIVANOV

STONY METEORITE OF KAPTAL ARYK

The stony meteorite fell on May 12 1937 at about 16 45 U T in the centre of the village of Kaptal Aryk (Kalinin, Kirghizian SSR) 42° 27 N and 73° 22 E The flight of a fire ball (bolide) of a slightly reddish colour was observed from which a large number of small sparks were scattered forming a bright trail instantly disappearing behind the fire ball

The fire ball was seen moving from east to west All the phenomena of the fall lasted not more than two or three seconds At the beginning a din was heard, resembling that produced by the flight of several aeroplanes , then a deafening detonation was heard, audible at a distance of 20–30 km The flight of the fire ball was noted at Frunze within a distance of 70 km from the place of fall No marked illumination of the country was observed , the illumination within a distance of 45 km from the place of fall (at the Karl Marx collective farm) resembled moonlight The meteorite penetrated 60 cm. into the hard soil of the street

On the surface the stone has a black smooth crust about 0 5 mm thick, and characteristic piezoglypts The inner mass of the stone is traversed by closely spaced black veins On the fracture surface grains of nickel iron are perceptible

The initial weight of the meteorite is estimated at 3 5 kgm The meteorite may be provisionally referred to the veined chondrites The total weight of the three parts of the meteorite delivered to the Academy of Sciences of the U S S R is 2 904 kgm

* Communicated by Dr W Vernadsky chairman of the Meteorite Committee of the U S S R Academy of Sciences

STONY METEORITE OF LAVRENTIEVKA

On January 11, 1938, at about 10.30 U.T., a meteorite of a lens-like shape, weighing about 1¼ kgm. was seen to fall near the village of Lavrentievka, Orenburg region (52° 27′ N., 51° 34′ E.).

The meteorite fell within a distance of 18–20 metres from T. A. Zhigunov, a hunter, who picked it up immediately. Previous to the fall this witness heard in a northerly direction a din with three detonations following each other at equal intervals, each subsequent stroke being stronger than the one preceding it.

The detonations preceding the fall of the stone were heard by many of the inhabitants of the village of Lavrentievka and other neighbouring villages. However, neither T. A. Zhigunov nor anyone else observed any light phenomena, although the sky was perfectly cloudless.

The stone fell on a frozen ploughed soil not covered with snow; it penetrated only 5 cm. into the soil. During the fall the stone scattered on different sides clods of frozen earth over an area up to two metres in radius; in addition, as observed by T. A. Zhigunov, the stone itself was for some time revolving about its axis.

Two minutes after the fall, T. A. Zhigunov picked up the stone and felt it to be too hot to be held in a clenched hand; therefore he placed it on the ground; in about ten minutes the stone had cooled to such an extent that it could be readily taken in the hand.

During the fall, a small chip was split off from the stone. Later on, three more small pieces were broken from it. All these pieces, placed together with the bulk of the stone, reproduce the original lens-like shape of the stone.

The weight of the four fragments of the stone thus assembled is 793.60 gm. Moreover, probably 200 gm. were lost in the crushing of the stone.

The meteorite may be referred to white chondrites and contains a rather large number of chondrules and metallic grains. The mat smooth crust of the meteorite is of a black-brown colour and has no piezoglypts.

The study of this fall was made by the present writer. The five fragments of the meteorite mentioned above have been placed in the meteorite collection of the Academy of Sciences of the U.S.S.R.

E. L. KRINOV

Greek Earthquake of July 20, 1938

SUDDENLY and without any premonitory tremors in the early morning of Wednesday July 20 a very large area centred in northern Attica, Greece, was disturbed by a violent earthquake (see NATURE, July 30, p. 202) which did much damage to property and caused the deaths of twenty people and injuries to a hundred others. It is now possible to add some further details of this shock from a preliminary report prepared by Prof. N. Critikos of the University of Athens, though the final conclusions will not be available for some time.

The first pulses to reach the seismological observatory at Athens did so at 2h. 24m. 19s. (T.m.E.O.), and thus the initial time of the shock must have been 24m. 13s. ± 2s. The pulses immediately succeeding these were of such violence that both seismographs at the observatory were forced from their bearings and damaged. The 1,000 kgm. Wiechert horizontal pendulum was so seriously damaged that it took several days to repair, but the 1,200 kgm. Wiechert vertical instrument was put right almost immediately, and was registering again about one and a half hours after the initial shock. This latter instrument registered small aftershocks at intervals of five or ten minutes for several hours.

The very strong tremors were felt by people in Athens to last 8–10 seconds, being preceded and accompanied by quite loud deep-toned underground rumblings. The preliminary movement appeared to be horizontal and then undulatory with a slight diminution of intensity towards the middle of the duration. It appeared to come from the north-north-east and to be travelling to the south-south-west. On the coast at Scala Oropos, in the epicentral region, the intensity of the shock was much stronger and it also appeared to last longer. The region over which the shock was felt macroseismically extended as far as the island of Lemnos (Castro), that is, more than 250 km. in this direction, but in the perpendicular direction scarcely 140 km. to Lamia Syra. Thus the epicentral region was elongated in a north-east–south-west direction. The villages affected slightly in Attica were Kakossalesi, Malakasa, Kapandriti, Kiourka and Kalamos, whilst the villages in which most damage was done include Scala Oropos (with Nea Palatia and Pontion), Chalcoutsi, Oropos and Sycaminon.

From the above evidence it appears that the epicentre was near the north coast of Attica at a distance of 42.5 km. from Athens and near a point having geographic co-ordinates lat. 38.35° N., long. 23.8° E. The fact that the seismic energy was propagated to a greater distance in a north-east–south-west direction, that is, in the direction of the great tectonic fault which passes between Mt. Pentelica and Mt. Parnes, suggests that there was a sudden vertical movement of this fault resulting from a positive orogenic movement.

The earthquake has been followed by numerous feeble aftershocks only one or two of which have been felt as far as Kapandriti, Tatoi, Eretrie and Chalcis. Another shock, of moderate intensity, and having the same epicentre, took place on July 27d. 3h. 29m. 19s. (T.m.E.O.) and was just sensible in Athens. Slight aftershocks were continuing infrequently even on August 12.

Although Greece as a whole is liable to earthquakes, the region near and to the north of Athens has not been considered as being active seismically on a destructive scale in recent times. Modern research, however, indicates that it was probably a seismically active region during the seventh and eighth centuries A.D., and this activity appears to have been renewed in the present instance.

The damage done during the earthquake of July 20 was serious chiefly to old and/or badly constructed buildings. An interesting case concerns the primary school at Kalosalesi, the walls and roof of which appear to have moved independently, causing great damage at junctions.

Epidemics in Schools*

THIS volume constitutes an interim report of a committee appointed by the Medical Research Council seven years ago to investigate the subject of epidemic and other illnesses in schools from both the scientific and practical points of view. Of the schools investigated, twenty were public schools for boys and seventeen for girls, the majority of the pupils being boarders, and the social class being very similar in both. Most of the pupils had been to preparatory schools, so that there was no sudden change in environment—from the family to school—and were between thirteen and eighteen years of age. The criterion of sickness adopted was that causing at least one day's absence from school.

The following are some of the points that emerge from the enormous amount of data collected and analysed. Nasopharyngeal infections from the attack rates seemed to be more prevalent among the girls; but this is apparently not because girls are more susceptible than boys, but because the girls are subjected to stricter surveillance. The common cold was one of the most important causes of lost time, and if influenza is included, making one group of "nasopharyngeal infection", accounts for as much as 53 per cent among girls, and 43 per cent among boys, of all time lost on account of minor respiratory troubles. Epidemic influenza was almost confined to the Lent term, and many other diseases showed a tendency to be concentrated into this term. The incidence of injuries was heaviest among boys in the Christmas term; but whether this is due to intensified activity as a result of good health, or to more football in this term, is uncertain. Boys suffer twice as frequently from middle ear disease, two and a half times as frequently from pneumonia, and eleven times as frequently from acute rheumatism, compared with girls. There is no evidence as to the cause of this greater incidence upon boys; it may be a real sex difference, but it may in part be due to the fact that girls are under stricter supervision. More than half the boys and half the girls had had their tonsils removed, but there is no evidence that wholesale tonsillectomy results in a diminished incidence of nasopharyngeal and some other diseases.

In regard to the apparent relation between herpes zoster and chicken pox, it is of interest that in eighteen out of twenty occasions when zoster preceded chicken pox, the first case of chicken pox might, from the point of view of time, have been infected from a case of zoster.

Dr Lempriere contributes an interesting historical introduction on the medical history of public schools, and Dr Griffith a section on the bacteriology of otitis media and mastoid disease, pneumonia and streptococcal infections, with determinations of the types of micro-organisms present in these infections.

Work of the Forestry Commissioners

PERHAPS the most interesting part of the eighteenth annual report of the Forestry Commissioners for the year ending September 30, 1937 (London: H.M. Stationery Office. 1*s*. net), is the account of the work undertaken to give effect to the Government policy for the Special Areas in connexion with afforestation. In the previous annual report (to September 1936) reference was made to the initiation of a scheme of afforestation and forest workers' holdings in the Special Areas of England and Wales. It was then pointed out that both the acquisition of the necessary land and the provision of plants would take time, so that no large scheme of afforestation could be anticipated during the present year.

The scheme proposed envisaged the acquisition of 100,000 acres of plantable land, its afforestation and the formation of 500 forest workers' holdings in three years. This proposal was regarded as an experimental step which, if successful, would be followed by a larger scheme covering 200,000 acres and 1,000 holdings to be put through in ten years.

At the close of the year under review, 568,000 acres were examined in or within a 15-mile radius of the Special Areas, namely, 225,000 in the Northern Area (Durham, Tyneside, Haltwhistle and West Cumberland) and 343,000 in the South Wales Area. Of this area, 72,000 acres in the north and 80,000 acres in South Wales were found to be subject to rights of common and so not available for the purpose in view. On the whole, owners of land were favourable to the scheme. By the end of the year, 42,900 acres of plantable land had been acquired spread in nearly equal amounts between the two regions.

Nursery work had to be considerably extended and a large new nursery has been established at Tair Onen in the neighbourhood of Cardiff. At this nursery no less than seventeen forest workers' holdings have been established. Although probably but little known to the public, this side of the activities of the Commission is by no means the least interesting, for the work has been brought to a high level of efficiency.

Owing to a shortage of plants it was not found possible to carry out the additional planting work either during the season of 1936–37 or that of 1937–38; in the latter year the projected programme of 3,350 acres being reduced to 3,000 acres. It is added: "Except for any ill-effects due to the prolonged drought of the spring of 1938, plant supply should not in future be a limiting factor". It is to be feared that in some parts of the country at least there will have been a considerable mortality, both on

Government and private estates, in connexion with the plantings of early 1938

During the course of the year, the report states, 'an interesting landmark, the million acres, was passed, the total acquired to the end of the year being 1,008,500 acres

The report contains some interesting remarks on amenity and the opposition of local bodies to afforestation work in what are considered 'beauty spots, on national forest parks and on private woodlands—all points of considerable interest to the general public The Commission is now engaged in undertaking a census of woodlands in Great Britain, the last census, a somewhat inadequate one, having been undertaken in 1924

St. George's Day among Serbian Gypsies

ST GEORGE S DAY (Djurdjev Dan) is of all 'Slavas' that most enjoyed by the Gypsies of Serbia This feast, Dr A Petrović says in his continuing study of the Serbian Gypsies (*J Gypsy Lore Soc*, Ser 3, 17, 2, 1938), is not only a holiday, but also a harbinger of spring and new life—first of all with respect to food when new vegetables are available, from which a woman, using salt and a little bread will make a salad to last a family for a whole day It is also the time when the gypsies cease to sleep in the house and take their bedding and the anvil outside They sit, eat and sleep in the open air

In the old days, when many Serbian gypsies had no permanent dwelling places on October 26 O S (St Demetri s Day) they used to select the village in which they would stay for the winter, but as soon as spring had come, all left their winter quarters to meet at some previously appointed spot on Djurdjev Dan One such place was Mirijevo, near Belgrade At such a meeting two to three hundred tents of gypsies would be gathered together Every family slew a sheep for the ceremonial meal In this meal the whole body of the sheep was brought to the table with the horns still on the head to show how large the sheep had been The larger the horns, it was believed, the bigger the sheep All the gold and silver coins the family possessed were hung around the neck of the roasted sheep, indicating what sort of a year the host had had After this followed greetings and questions as to the happenings of the preceding year Marriages followed Eating, drinking and revelling lasted the whole day In this manner they said they were seeing the winter off down stream, along the Danube

At Kopljari, on the eve of St George, a thread was taken and hung for a time on a rose branch It was then fastened around the neck of a child, where it was left until it broke Members of the family gather and weave garlands of flowers, one being thrown on the wood shed for storing maize with the words "Let the shed be full of maize" Another is thrown on the corn loft with a similar formula At night one of the men goes to the field of a rich man and gathers green corn, which he then throws on his own fields, with a formula expressing his desire to become a "master", as the man from whom he has stolen the corn A branch stolen from another man's tree is made into a cross and painted to ensure fertility "like that of the hazel nut" An elaborate ceremonial is observed in preparation for the feast, and all must first bathe naked in the river.

Science News a Century Ago

The Entomological Society

AT a meeting of the Entomological Society held on October 1, 1838, J F Stevens, president, being in the chair, The Rev M Taylor presented specimens of the different sexes of a species of wasp, and of *Ripiphorus paradoxus*, a singular species of beetle which is parasitic in their nest An extended discussion in which several members joined, took place relative to the hexagonal formation of the cells of bees and wasps in reference to Mr Waterhouse's theory upon the subject The following memoirs were read 'Notes upon the Egg Cases of the Blattæ and their Parasites by Mr Sells 2 A few words in reply to Mr Macleay s Remarks upon the Metamorphoses of Crustacea, by Mr Westwood 3 Observations on the Habits of the Œstridæ by Mr Sells "

Charles Tennant (1768-1838)

ON October 1, 1838, Charles Tennant, founder of the chemical firm of Charles Tennant and Co Ltd, died at Glasgow at the age of seventy years Born at Ochiltree, Ayrshire, on May 3, 1768, he was educated at the parish school and was then set to learn silk manufacturing When twenty years of age he became the managing owner of a bleaching field at Darnley near Paisley, where he discovered a method of controlling chlorine gas by the admixture of lime His discovery led to the abandonment of the old processes of boiling the cloth in weak alkali and of exposing it to the sun and air for several days and effected great savings In 1800, with the aid of four partners, he established the famous works at St Rollox, Glasgow

Although Tennant was unsuccessful in upholding the validity of his patent in the courts, his services to industry were acknowledged by the bleachers of Lancashire presenting him with a service of plate A history of the firm he founded was published in 1922

Science in Austria

ON October 6, 1838, the *Athenæum* published an article by its correspondent in Germany, who referred to science in Austria 'It is a remarkable fact,' he wrote, that Vienna is the only European capital in which there is no academy or association for the cultivation of science, organised under the sanction and encouragement of the State " Leibnitz had made an attempt to found such an institution and a plan was brought forward under Maria Theresa in 1773, but "nothing further was dreamt of the special cultivation of science in Austria, till last year, when twelve men, well known for their learning and abilities presented, by the hands of the Archduke Lewis, a petition for the establishment of an Academy of Science at Vienna These twelve men were—Jacquin, Littrow, Prulite, Baumgartner, Ellingshausen, and Schreiber, as representatives of the Mathematical and Physical class, and Kopitar, Wolf, Buchholz, Arneth, Chonel, and Hammer-Purgstall, for the Philological and Historical class No notice has, we believe, been taken of this petition, and we presume that Prince Metternich does not deem it becoming in a fond and paternal government to give its subjects the pain of thinking "

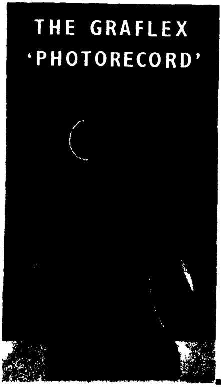
UNIVERSITY PRESS



An indispensable unit for Photorecord Work

The Graflex 'Photorecord' offers a speedy and accurate means of making all kinds of photographic records documents, X-rays, written and printed data, as well as identification records of people, surgical operations, etc Camera and lighting equipment are easily adjustable to suit any circumstances and up to 1,600 successive pictures can be taken on economical 35 mm film

The Camera f3 5 lens—Shutter speeds 1½ to 1/25th second and Time' Takes 100-foot lengths, or less, of 35 mm film Automatic operation Adaptable for cut film and plate holders Accurate focusing

The Lighting Flexible supports for correct positioning Revolving reflectors ensure balanced illumination Photoflood lamps of variable intensity

Uses for the Graflex 'Photorecord'

For copying case records, correspondence, documents, etc
For duplicating X ray negatives and other material
For taking pictures of slides and specimens through a microscope
For making identification portraits, recording the progress of disease, growth, etc
For recording the successive stages of operations

The Promotion of Peace

THE agreement arrived at by the four-power conference, which met at Munich on September 30 to find a peaceful solution of the conflicting rights of Czechs and Germans to territory assigned to Czechoslovakia by peace treaties which followed the Great War, marks the beginning of a new era in the history of the world, and will be gratefully welcomed by scientific workers in natural and national fields as a significant stage in the progressive ethical evolution of the human race

The British people have expressed their enthusiastic admiration for the self-sacrifice and unceasing endeavour exercised by Mr Neville Chamberlain, the Prime Minister, to secure this end Suggestions have been made that a national tribute fund should be opened, and Sir Charles Hyde has put at the disposal of the University of Birmingham the sum of £10,000 to provide a Neville Chamberlain fund or scholarship Appropriate recognition, independent of nationality, could be given by the Nobel peace prize, which is awarded "to the person who shall have most or best promoted the fraternity of nations and the abolition or dissemination of standing armies and increase of peace congresses"

The immediate object of the meeting between Mr. Chamberlain, M Daladier, Herr Hitler and Signor Mussolini, reinforced by letters from President Roosevelt, was to find a peaceable settlement of a bitter dispute between Czechs and Germans, and though the people of Czechoslovakia naturally regard the terms imposed upon them as harsh, they and other nations would suffer far more if active hostilities had eventually to determine them Even more important than the agreement of the four great European powers as to new boundaries between Germany and Czechoslovakia was the declaration signed by Mr Chamberlain and Herr Hitler as the result of a further talk

"We regard," it says, "the agreement signed last night and the Anglo-German Naval Agreement as symbolic of the desire of our two peoples never to go to war with one another again We are resolved that the method of consultation shall be the method adopted to deal with any other questions that may concern our two countries, and we are determined to continue our efforts to remove possible sources of difference and thus to contribute to assure the peace of Europe"

This is, indeed, a step forward in the promotion of peaceful methods of settling disputes between nations, and however much we may deplore the intolerance of intellectual freedom, and the persecution of a defenceless minority, by which Germany is suppressing the advancement of knowledge and the rights of man, the declaration of the new Anglo-German undertaking makes the outlook much brighter. Sixty years ago, another Prime Minister, Disraeli, avoided a war between Russia and Britain by the Treaty of Berlin, as the result of consultation with the councils of Europe, and secured his "peace with honour" We hope and believe that the resolution now made between the German Fuhrer and Chancellor and the British Prime Minister will have more lasting influence than that reached by Disraeli, of whose treaty it was said soon afterwards.

"Once 'peace with honour' home was brought;
  And there the glory ceases,
For peace a dozen wars has fought,
  And honour's all to pieces."

The Cyclotron and its Applications*

By Prof. J. Chadwick, F R S

IN the early work on the artificial disintegration of elements by α particles it was thought that particles of very high energy were necessary in order to penetrate the nuclei of even the lighter elements and there appeared little if any hope of ever extending these experiments to the heavy elements

The application of quantum mechanics to the problem of the penetration of potential barriers however indicated that particles of comparatively low energy should have a small but not negligible probability of entering the nuclei of the light elements Now the small chance of penetration can be compensated by using large numbers of particles and Cockcroft and Walton realized that this might make it possible to observe disintegrations with particles of energy of only a few hundred kilovolts They carried out the first successful experiment of this kind in 1932 when they observed the disintegration of lithium under the bombardment of protons Using potentials up to 600 kv to accelerate the ions obtained from a hydrogen discharge tube they were able to disintegrate several of the lighter elements They were however unable to produce disintegrations in the heavier elements The reason for this limitation is that the height of the nuclear barrier opposing the entry of the proton increases with the atomic number of the element In order to disintegrate the heavy elements we must use particles of much greater energy than those used by Cockcroft and Walton In fact we require accelerating voltages of some millions of volts instead of some hundred thousands

During the last ten years several methods have been developed for accelerating ions—protons deuterons or α particles—to the very high energies necessary for these experiments on the transmutation of elements The methods may be divided into two classes the direct methods in which a high voltage is developed and applied to a discharge tube and the indirect methods The direct methods have some serious disadvantages First they are limited to what for the present purpose are moderate voltages Experimental difficulties increase rapidly as the voltage is increased and so far the highest voltage which has been used directly for the acceleration of ions is two million volts Secondly high voltage outfits need much space The cost of installing an outfit operating at say 5 million volts would be very high for the building alone for few if any physical laboratories possess the large and lofty hall which is necessary to house such an apparatus

In the indirect methods of accelerating ions a relatively small voltage is applied many times in succession increasing the energy of the particles in a series of small steps

The most successful of these indirect methods is that used in the cyclotron or magnetic resonance accelerator which has been developed by Prof E O Lawrence and his collaborators in the University of California

Suppose a particle of mass m and charge e moves with velocity v in a plane at right angles to a magnetic field H The particle will move in a circular path of radius ρ where ρ is given by

$$mv^2/\rho = H e v$$

The time taken to complete a revolution is

$$\frac{2\pi\rho}{v} = 2\pi \frac{m}{e} \frac{1}{H}$$

The time of revolution does not depend on the radius of the path or on the velocity of the particle For ions of the same e/m the time of revolution will always be the same in the same field

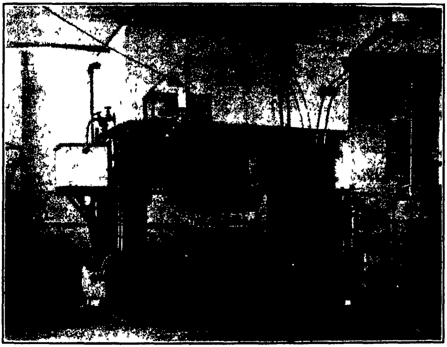
Now suppose that we have in the field two electrodes between which we can apply an alternating voltage V Let an ion start with very small velocity at some point between the electrodes If the top electrode happens to be positive at that moment the ion will be driven downwards It will travel in a semi circular path and return to the gap between the electrodes Its energy will be eV If at this moment the top electrode is negative it will be driven upwards acquiring another increment of energy eV Since the particle always takes the same time to go round the semi circle and return to the gap it should be possible by adjusting the frequency of the A C voltage and the strength of the magnetic field to keep in step with the particle that is to give the particle an impulse every time it crosses the electrodes

Whether this method is possible in practice will depend first on whether one can produce oscillating voltages of the required frequency Let us calculate what frequency is required for a proton

---

* From the Friday evening discourse given at the Royal Institution on May 27

The time of rotation is $2\pi . \frac{m}{e} . \frac{1}{H}$, and for a proton is equal to $6{\cdot}57 \times 10^{-4}/H$ sec The final velocity of the proton is proportional to $H\rho$, where ρ is the radius of its final orbit Since it is desirable to keep the dimensions of the apparatus—and especially the dimensions of the magnet—as small as possible, H must be large With good mild steel, H may be as much as 19,000–20,000 gauss Let us take H equal to 15,000 gauss as a readily attainable strength of field Then the time of rotation is $4{\cdot}38 \times 10^{-8}$ sec. The frequency of the alternating field must therefore be $2{\cdot}28 \times 10^{7}$ cycles per sec, corresponding to a wave-length of about 13 metres



Magnet of the Liverpool cyclotron

The photograph, taken at an early stage in the construction of the cyclotron, shows the magnet assembly with its water supplies, etc, but without the vacuum chamber and its auxiliaries

As the time of rotation is proportional to m/e, the frequencies of the oscillations required to accelerate deuterons or helium ions (α-particles) under the same conditions will be half as great, corresponding to a wave-length of 26 metres.

We have now to calculate what speeds the particles can acquire in this way. The maximum velocity is determined by $H\rho$, that is, it depends not only on the strength of the field but also on its extent. In the magnet at Liverpool the diameters of the pole faces are 94 cm., and we can allow ρ to be about 38 cm. With H equal to 15,000 gauss, the proton would reach a speed of $5{\cdot}4 \times 10^{9}$ cm/sec, or an energy of 15 million volts. Under corresponding conditions, deuterons would acquire an energy of 8 million volts

At first sight it seems that exceedingly high energies might be reached, for it is quite feasible to increase H to 20,000 gauss and ρ to 60 cm, or more A proton of $H\rho$ equal to $1{\cdot}2 \times 10^{6}$ would have an energy of about 60 million volts However, a serious difficulty appears when the protons move at a speed corresponding to more than about 10 million volts (deuterons at about 15 million volts) This difficulty arises from the relativity increase of mass of a particle with its speed The relation $H\rho = mv/e$ is no longer sufficiently precise, and we must write

$$H\rho = \frac{m}{e} \frac{v}{\sqrt{1 - v^2/c^2}}$$

The particle will not keep in step with the electrical oscillations, that is, there will not be resonance One could try to obtain exact resonance by adjusting the magnetic field so that it increases gradually as ρ increases, but this introduces another defect which may result in complete loss of the ion beam. It may prove possible to find a suitable device to overcome these troubles, but at the present moment it seems that limits are set to the energies which it is feasible to reach, about 10 million volts for protons, 15 million volts for deuterons and α-particles Even these limits have not yet been quite attained.

The possibilities of the cyclotron are so outstanding that, in spite of the expense and labour of construction, many machines have been or are being built in laboratories all over the world In Great Britain there are two cyclotrons nearly ready for use, one in Cambridge and the other in Liverpool. It may be of interest to give a few details of the construction of the Liverpool cyclotron, although it is not yet in operation.

The electrodes between which the ions are accelerated are two short, hollow semi-cylinders of large diameter, about 2 inches high and about

30 inches diameter made of copper sheet These known as the *D* plates are contained in a large chamber or tank Hydrogen (for a proton beam) or heavy hydrogen (for deuterons) is admitted to the tank so that a pressure of about 10^{-4} mm is maintained

The ions are produced at the centre of the chamber between the *D* electrodes by bombarding the gas with an intense stream of electrons from a heated filament

The alternating voltage is applied to the *D*s by coupling them to an oscillating circuit The generator of the oscillations consists of two large triode valves coupled in push pull using a self oscillating circuit It is important to make the voltage difference between the *D*s as high as possible and therefore the oscillation generator must be able to supply a considerable amount of power certainly more than 20 kw The voltage between the *D*s in Lawrence s experiments is about 45 000 volts

The vacuum chamber containing the *D* plates etc is placed between the poles of an electro magnet As it is important in order to obtain resonance that the field should be uniform over the whole path of the ions the diameter of the poles must be sensibly greater than that of the *D* plates The magnet must therefore be very large and a fair amount of power will be required to maintain the magnetic field Our Liverpool magnet contains 46 tons of iron and 8 tons of copper (The copper was generously presented to me by the directors of British Insulated Cables Ltd) The diameter of the pole faces is about 36 inches and the air gap between them is 8 inches The power consumption in normal running conditions will be from 40 to 50 kw under full load about 70 kw The maximum field under the conditions of experiment that is with a working gap of 5 inches is about 19 000 gauss

When the ions come to the periphery of one of the *D*s they are allowed to pass through an opening where the *D* is cut away An electric field is applied between a plate—the deflector plate—and the *D* to deflect them from their circular path towards a window in the tank The ions can thus be brought out of the tank and made more readily available for experiment

The intensity of the ion beam which is obtained in this way depends of course on the number of ions produced initially at the centre of the chamber It depends also on a very careful adjustment of the magnetic field by means of which the ions are concentrated near the median plane of the *D* plate In Lawrence s early experiments the ion current was of the order of 0 01 microampere Now by improvement of the conditions Lawrence can maintain an ion current of 150 micro amperes for many hours The number of particles carried by such a current is 10^{15} per second equal to the number of α particles emitted by 30 kgm of radium Moreover the energy of the particles is greater—about 8 million volts—nearly double the energy of the fastest α particle from radioactive bodies

THE APPLICATIONS

When the stream of fast particles—protons deuterons or α particles—issuing from the cyclotron is allowed to fall on a target of an element some of the atomic nuclei may undergo transmutation The incident particle enters the nucleus and a new nucleus is formed which disintegrates with the emission of a different particle In many of these transmutations neutrons are emitted and these in their turn can be used as projectiles for the transmutation of elements

The general processes of nuclear transmutation are well known and need not be described in detail here It will be sufficient to note that more than four hundred nuclear reactions of this primary type have already been discovered Many new forms of atomic nuclei have been produced in these reactions Nearly all these new atomic nuclei are isotopes of the ordinary chemical elements They differ from the known isotopes in that they are unstable and transform in the course of time with the emission of a negative or positive electron into a stable nucleus This is the phenomenon of artificial radioactivity discovered by Mme and M Curie Joliot Such changes as these may be called secondary nuclear reactions About two hundred or more cases of this type are known some of which are of special interest

In general terms one may say that the physical applications are directed to the study of atomic nuclei their transmutation by bombardment with different nuclei the investigation of the properties of neutrons and of the interaction of fast particles with matter

I should like however to refer to certain applications of the cyclotron which depend on these nuclear reactions and in particular to the biological applications

One may draw an analogy between the cyclotron and the X ray tube In the X ray tube the stream of electrons is used to produce X rays the fast ions issuing from the cyclotron can be used by bombarding beryllium for example to produce a stream of neutrons When we remember the uses of X rays and of radium in the treatment of malignant tissues it is natural to ask what are the possible applications of neutrons

The ionizing effects of neutrons are rather different from those of X rays The X rays impart their energy to the electrons of matter through which they pass and these secondary electrons produce relatively small ionization over a long path Neutrons do not lose energy in collision with electrons but in collision with the nuclei of atoms In passing through living matter neutrons will lose energy mainly in colliding with the hydrogen atoms producing recoil protons which ionize very strongly over a short path For example 2 M e v neutrons passing through tissues will frequently produce recoil protons of about 300 000 volts energy These will produce about 10 000 ions in a distance of some 4–5μ A secondary electron produced by X rays would give less than 100 ions in the same path

It seems that biological effects on individual cells depend more on ionization density than on the total number of ions and therefore one might expect that neutrons will be biologically more effective than X rays giving the same total ionization There is a certain amount of evidence which indicates that this is indeed the case but the results are too meagre to permit a definite conclusion For a given ionization neutrons appear to be about five times as effective as X rays in destroying malignant cells or in changing the blood picture of the rat and about ten times as effective in retarding the growth of wheat seedlings Many experiments are now in progress both on plant and on animal tissues

By means of neutron irradiation it may be possible to produce biological effects in specific regions There are some elements which show strong absorption of slow neutrons for example lithium and boron Ordinarily animal tissues do not contain any significant amount of these elements but it may prove possible to inject into the tissues in a suitable form compounds of such elements Irradiation of the tissues with slow neutrons would then cause the release of considerable energy in the small volume containing the injected substance

RADIOACTIVE INDICATORS

Another aspect of the application of the cyclotron to biological investigations arises from its use in the production of artificial radioactive elements Nearly all the ordinary chemical elements can now be obtained in radioactive modifications These have exactly the same chemical properties as the usual forms The radioactive isotope will accompany its inactive isotope through any series of chemical processes however complicated these may be but the active isotope can always be recognized by its radioactivity which acts as a label enabling us to detect the presence of a particular group of atoms and to follow this group throughout the chemical processes Thus if we wish to study the distribution of a certain element in a series of biological processes we can mix with it a radioactive isotope and we can follow the distribution by means of the radioactivity

Up to the present the use of active indicators in biological investigations has been almost entirely confined to the role of phosphorus in metabolism Apart from its structural function along with calcium as a major constituent of bones and teeth phosphorus as phosphoric acid plays a predominant part in the intermediate metabolism of a variety of substances An active modification of phosphorus can be produced in different ways one of which is the deuteron bombardment of phosphorus

$$_{5}P + {}^{2}H \rightarrow {}_{5}P + H$$
$$^{32}_{5}P \rightarrow {}^{32}_{6}S + {}^{0}e$$

The radio phosphorus breaks up with the emission of a β particle and the formation of ^{32}S It decays to half value in 14½ days a very convenient period

Radio phosphorus was first used as an indicator by Chiewitz and Hevesy in the study of phosphorus metabolism in rats The active phosphorus is mixed with inactive phosphorus and converted into sodium phosphate This can be mixed with the food of the rat The fate of the phosphorus—whether excretion deposition transfer from one tissue to another and the biological synthesis of compounds which contain phosphorus—can then be followed by tracing the radioactive atoms

In this way it was found that a large part of the phosphorus was incorporated in various compounds in the bones and muscles from which it is gradually displaced The experiments confirm the idea that the mineral matter of bone is in a dynamic state in which the bones are continually losing phosphorus atoms and taking up others which are later in their turn replaced

Another example of the use of phosphorus is given by an experiment of Hahn and Hevesy It is generally assumed that no regeneration of the brain tissue of adult animals takes place Hahn and Hevesy found however that one hour after a subcutaneous injection of labelled sodium phosphate labelled lecithin was already formed in the brain tissue of fully grown rats Their experiments suggest that a constant breakdown and building up of lecithin takes place in the brain tissue

These examples are sufficient to show that by the use of radio phosphorus as an indicator it is possible to provide a ready answer to such questions as How much of the phosphorus taken in by the body at a given moment reaches the bones or teeth ? How long does it take to arrive there ?

By what path does it arrive ? How long does it stay ? How does the distribution of phosphorus depend on abnormal conditions of diet or disease ?

Investigations such as these are now beginning in various laboratories They will not be restricted to the study of phosphorus for other elements of interest in bodily metabolism such as calcium potassium iron etc are available in active modifications I think it is clear that this method of radioactive indicators has many interesting possibilities for its power and delicacy make it possible to attack problems which have so far been inaccessible to experiment

There are also other applications of the radio active modifications of suitable elements If an element is concentrated in certain organs then these organs can be subjected to selective irradiation by using an active isotope of the element For example radio phosphorus can be used to irradiate bone and bone marrow or spleen radio iodine for thyroid etc So little work has been done on these lines that it would be premature to discuss these therapeutic applications further They may however prove to be important and among the most spectacular results of experiments on artificial transmutation

History of the Fenland*

WITHIN historic times the English fenland stretched over the greater part of the area to the west and south of the Wash extending as far north as Lincoln and as far south as Huntingdon and Cambridge On the seaward side the surface deposits are semi marine silts laid down and afterwards occupied during the Romano British period On the landward side the upper layers are peat produced by discharge of the flood waters of the Rivers Witham Welland Nene and Ouse into the extensive shallow basin of the fens The fen peats are alkaline and therefore support a vegetation of the true fen type Very little of the original vegetation of the peat fen remains however since the whole area has been drained and brought under extensive cultivation Its present characteristics are the black peaty soil uniform flatness and deep ditches full of reeds (*Phragmites communis*) which separate fields of cereals potatoes and sugar beet

Cambridge is at the head of the fens and the town and University have become the centre of the activities of the Fenland Research Committee formed in 1932 under the presidency of Sir Albert Seward and aided by grants from the British Association the Percy Sladen Trust and the Department of Scientific and Industrial Research Thus have the geology botany archæology stratigraphy and climate of the fenland area been closely investigated One fen area which has yielded exceptionally valuable results is Wicken Fen the largest area still uncultivated covering about one square mile now in the hands of the National Trust and lying about ten miles to the north east of Cambridge on the margin of the fenland itself

Very little is known of the fenland in glacial times for most of our knowledge of the area we must turn to the post glacial period during which the most important single key to its history lies in the recognition of the land and sea level movements which have left their record in the deposits of the basin

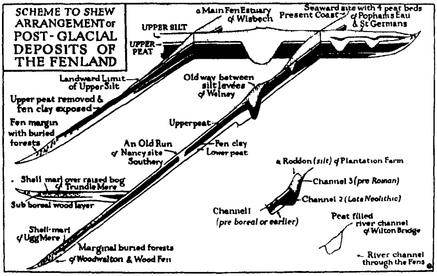
The upper layers are very similar to those of the German coastal marshes Although the peat is continuous at the margin it is soon separated into an upper and lower layer by wedging out of soft grey clay The lower layer contains brushwood of oak pine and alder the upper layer contains some tree remains and above this a layer of *Sphagnum* peat of a type similar to that of the large red bogs of the central Irish plain In certain parts there is a layer of calcareous shell marl overlying the *Sphagnum* peat This reflects very changed conditions since *Sphagnum* could not have grown in water so deep or so calcareous From investigations of the diatoms and foraminifera of the fen clay it is concluded that it was deposited in brackish water and that there was also considerable marine influence This shows that a phase of freshwater peat formation with fen woods was interrupted by a marine transgression and that after the upper peat had formed a phase of increased wetness produced shallow lakes

In places nearer the sea there is upper silt several feet thick and several feet above sea level Its foraminifera content shows it to represent another marine phase The upper peat extends below it at about ordnance datum for many miles seawards The surface of this silt shows abundant traces of Romano British occupation In parts the upper peat has been worn away by drainage and cultivation exposing the surface of the fen clay at ordnance datum Thus evidence is found of two periods of freshwater conditions and two periods of marine transgression as major phases in fenland history.

---

* Based on the evening discourse by Dr H Godwin to the British Association at Cambridge on August 19

The lowest and oldest deposits of fenland, however, are out in the North Sea, where big deposits of moorlog have been discovered. These deposits have been found in water as much as 200 ft. deep, and have been shown to contain many species characteristic of the present-day fens or Norfolk Broads That these deposits may be looked upon as the earliest phase of fenland history has recently been established by the technique of pollen analysis By identification and statistical analysis of pollen in the deposits, not only can the species of plants be identified but also their periods of dominance For example, in south Germany there was an early phase of birch-pine dominance, then a phase of hazel, then a replacement of conifers by mixed oak woods followed by beech dominance, culminating in an increase in spruce and fir possibly to be attributed to the felling of beech in historic times



SCHEME TO SHEW ARRANGEMENT OF POST-GLACIAL DEPOSITS OF THE FENLAND
a Main Fen Estuary of Wisbech
Seaward site with 4 peat beds of Pophams Eau & St Germans
Present Coast
UPPER SILT
UPPER PEAT
Landward Limit of Upper Silt
Old way between silt levées of Welney
Upper peat removed & fen clay exposed
Fen margin with buried forests
Upper peat
An Old Run of Nancy site Southery
Fen clay
Lower peat
a Roddon (silt) of Plantation Farm
Shell marl over raised bog of Trundle Mere
Channel 3 (pre Roman)
Sub boreal wood layer
Channel 2 (Late Neolithic)
Channel 1 (pre boreal or earlier)
Peat filled river channel of Wilton Bridge
Shell-marl of Ugg Mere
Marginal buried forests of Woodwalton & Wood Fen
River channel through the Fens

From "A Scientific Survey of the Cambridge District", prepared for the Cambridge meeting of the British Association, and to be published under the title "The Cambridge Region" (Cambridge University Press, price 6s).

These phases of forest history have been correlated with archæological remains. For example, the Bronze Age was contemporary with the greatest expansion of beech, and the hazel maximum corresponded with the Tardenoisian. Forest history has been correlated not only with archæological horizons but also with climatic and geological events; thus is forest history dateable in years and may be utilized as an index to all kinds of events of the past For example, the analysis of a peat bed now buried under salt marsh on the Norfolk coast revealed a marked sequence of phases. To begin with, pine and birch dominated, then hazel, then pine which was later displaced by oak and elm and more especially alder. The last transition was at the Boreal-Atlantic level. Since this pre-Boreal peat is now 10 ft. below ordnance datum, the sea must have been 20 ft. lower in relation to land than it is now, but pollen analysis of the peat from the floor of the North Sea shows that it was in fact much lower than this The analyses made show only pine-birch with negligible amounts of other trees or hazel, and they almost certainly relate to the pre-Boreal They are from depths so great as 30 fathoms, so that it is very probable that at this time (about 8000 years B.C.) the North Sea was at least 200 ft lower in relation to the land than now, and the fens extended right over most of the present floor of the North Sea As the sea formed during the following centuries, more recent peats were restricted to the shallower coastal areas The considerable age of the deeper peats has been confirmed by the discovery of a bone fish spear of Mesolithic type in a lump of peat dredged by fishing boats from the Leman and Ower banks off the Norfolk coast.

The excavations and inquiries of the Fenland Research Committee have been limited to the more landward sites Of particular interest was the excavation of an ancient river channel at Shippea Hill, between Ely and Mildenhall Here, no fewer than three archæological horizons were discovered stratified into the fen deposits

Broadly speaking, the fenland history has shown alternating phases of marine invasion and of freshwater conditions The first freshwater phase in the present fens extended through the Mesolithic and Neolithic periods, and for much of the time the fens were covered with alder-birch fen woods. It was probably about the end of the Neolithic period that marine invasion caused formation of the fen clay. In the Bronze Age which followed, fen woods grew extensively, but these must have been dry enough for prehistoric man, since Bronze Age remains are found abundantly in the fen peats It is probable that the fens became too wet for occupation in the Iron Age.

In the Roman period, marine invasion once again dominated fenland history All the silt of the Wisbech Spalding area was laid down and its surface intensively cultivated Along the tidal rivers, silt banks were built up and stood above the surrounding peat land as habitable areas

After the Romans left Britain, the fens were not exploited until the drainage which began seriously in the seventeenth century As it became effective, the shallower lakes, such as Whittlesea Mere, Soham Mere and Benwick Mere disappeared The ground level sank by shrinkage and wastage of the peat, often as much as one inch a year, and the silt banks of the Romano British water courses began to appear as raised banks, or 'roddons', crossing the peatland

There is no reason for supposing that the land and sea movement, which has played such a large part in former fenland history, has now ceased entirely There is some evidence that recent drainage troubles in the fens are due in part to sinking of the coast It seems possible that the subsidization of work like that of the Fenland Research Committee would be of value not only to science in general, but also to such scientific applications as the drainage of the fenlands

Obituary Notices

Dr Charles Carpenter

BY the death of Dr Charles Carpenter on September 7 at the age of eighty years, industry loses one of its greatest administrators and applied science one of its staunchest advocates Trained from his youth as a gas engineer and with an intimate knowledge of gas engineering practice, his delight in precision caused him to realize the value of allying the scientific mode of thought to engineering practice It was this combination of science and practice which gave the keynote to his technical work The development of the Metropolitan Argand No 2 burner was an example of his personal interest in accuracy of detail and the desire to express a quantity so difficult of measurement as illuminating power with the greatest precision possible It was recognition of the need for closer co operation between the scientific and the practical man that led him to take so keen an interest in the work of the Society of Chemical Industry, of which he was president in 1915–17, and the dominating theme of both his presidential addresses was the necessity for bringing the often impractical chemist into closer touch with the engineer, whose work was incomplete without the co operation of a man viewing things from a more academic viewpoint

Dr Carpenter s belief that a vigorous chemical industry was necessary to the welfare of Great Britain was behind the strong support he gave to the formation of the Association of British Chemical Manufacturers During the Great War, his work as adviser to the Ministry of Munitions was made possible by the deep interest he had taken in the practical application of science, and when in 1917 the Advisory Council for Scientific and Industrial Research decided to establish a Fuel Research Board, Dr Carpenter was able to give material assistance in arranging for a site and facilities to be placed at the Board's disposal As a member of the Coal Conservation Committee appointed by the Ministry of Reconstruction in 1918, he showed his belief in the importance of applying scientific methods to the problems of fuel treatment and utilization The value of his work in designing and putting into production gas burners of standardized characteristics and of ensuring a gas supply unchanging in chemical composition and properties has, in later years received the recognition that it deserves, but the introduction of what seemed to many unnecessary refinements in the control of gas quality and in the removal of naphthalene and sulphur made him appear often to occupy a position of isolation among his contemporaries

As a pupil and the successor of Sir George Livesey, it was to be expected that the ideals of co-partnership should form the keynote of his relationship with the employees whom he controlled, and if Livesey planted a sapling, it is Carpenter who has cultivated it until it has grown to the dimensions of a healthy tree His career is throughout a record of pains taking devotion to duty inspired by ideals of honesty and fairness Entering the South Metropolitan Gas Co as an engineering pupil at its Vauxhall works, his unusual ability caused him to be appointed to the position of works engineer at the age of twenty six years, and on the death of Sir Frank Livesey in 1899 he was appointed chief engineer of the Company When in 1908 Sir George Livesey died, he was chosen by the Board of Directors to succeed him as their chairman, a position which he held, with the altered title of president, until ill health compelled his retirement in 1937

E V E

WE regret to announce the following deaths

Cavaliero Filippo de Filippi, Hon K C I E, a well known Italian explorer, who led the Italian expedition of 1913–14 to the Himalaya, Karakoram and Eastern Turkestan, on September 23, aged sixty nine years

Prof Derrick Norman Lehmer, emeritus professor of mathematics in the University of California, on September 8, aged seventy one years

Dr A S Mackenzie, president of Dalhousie University, Halifax, Nova Scotia, during 1911–31, formerly professor of physics in Bryn Mawr College, Dalhousie University and the Stevens Institute of Technology, aged seventy-three years

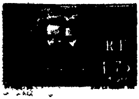
News and Views

Hugh Miller Commemoration at Cromarty

THE cottage at Cromarty in which Hugh Miller was born on October 10, 1802, was handed over to the National Trust for Scotland on September 26 The occasion was of interest not only to geologists but also to many who have been attracted to his writings by their highly individual style and charm and to those who are interested in the religious history of Scotland in the nineteenth century Few geologists have appealed to such a large reading public as did Hugh Miller, his assured place in the history of the science depends perhaps no less upon the stimulus and influence of his work than on its actual scientific content His apprenticeship to a stonemason turned his attention to the geology, and particularly to the sedimentary rocks, of the north east of Scotland He made the Old Red Sandstone a familiar term all over the world, and his book with that title 'amazed and delighted such an eminent geologist as Buckland Many of his other books were original attempts to make palæontology a contribution to Christian apologetics, Miller, as editor of the *Witness*, played a large part in the "non intrusionist" movement in the Church of Scotland Other collectors such as Robert Dick of Thurso (an acute observer who might, one feels, have rivalled Miller as a writer) looked upon Miller as their mouth piece, and their new specimens and information were often made known through him Miller's lack of orthodox anatomical knowledge was balanced by a "natural insight', and, even though much of his writing is now disregarded, his contributions to geology and to English letters form a durable record

Anniversary of the Discovery of Radium

THE fortieth anniversary of the discovery of radium is the occasion for the issue in France of a special postage stamp in honour of the discoverers, Pierre and Marie Curie Their lives and characters have been well revealed by their daughter Eve Curie, who wrote that her mother did not know how to be famous, while Einstein declared that Mme Curie alone of famous people was unspoiled by prosperity. Her other daughter, Irene, has carried forward the illustrious scientific work of her parents by her discovery, with her husband, Prof Joliot, of 'artificial' radioactivity The stamp, printed in blue, is excellent in design and carries faithful portraits, as may be seen by the accompanying reproduction It carries a surtax of half a franc for the benefit of the 'Union Internationale contre le Cancer On its merits, this stamp should have a wide appeal, enhanced by the desire to aid in the fight against a baffling disease



THE International Union against Cancer which comprises ninety two organizations representing fifty two nations, has succeeded in arranging for an International Week against Cancer on November 23–30, which it is hoped will take place simultaneously in fifty countries In connexion with the celebrations, an international commemoration of the discovery of radium, electrons, X rays and Hertzian waves will take place on November 23 at the Sorbonne, and a number of papers have been promised by distinguished scientific workers, including O Hahn (Berlin Dahlem), G Hevesy (Copenhagen), G P Thomson (London), M von Laue (Berlin), A Sommerfeld (Munich), J Errera (Brussels), F Carter Wood (New York), J D Bernal (London), H Stubbe (Berlin Dahlem), A Bouwers (Eindhoven) and L Marton (Brussels), in addition to French men of science Further particulars of the meeting can be obtained from the secretary general of the Semaine Internationale contre le Cancer 18 rue Soufflot, Paris (V)

Czechoslovakia's Future

DR GERALD DRUCE, who was the first English graduate of the Charles University of Prague after the Great War, writes as follows Relief that war has been averted is shared by the peoples of all nations Thanks to the uses that would be made of accumulated scientific knowledge and skill, a world war to day would be of such intensity and so ruthless that there would be no victory for the victors, whilst the vanquished might well suffer extinction Mankind has been mercifully spared this fate, but at the expense of a cultured and highly respected, if small, nation The Czechoslovaks have accepted proposals made without and against them", the economic and cultural consequences of which cannot be foreseen The territory ceded at once includes the whole of the Ore Mountains, so that the mineral wealth of north west Bohemia will no longer be available for the metallurgical and engineering establishments of Pilsen and Prague The pitchblende mines of Jáchymov (St Joachimsthal), together with the radium institute so largely developed by the Czechoslovak Ministry of Health, have also been lost In this area, too, the Aussig chemical concern has most of its plant and research stations The economic losses, of which the above are but examples, will necessitate curtailment of expenditure upon scientific and educational work in the residual State Hitherto, the Czechoslovak Ministry of Education has generously supported the universities and other scientific and educational establishments, but it cannot continue on the same scale that has hitherto been possible From the maps published in the Press, it appears that Brno (Brünn), the capital of

Moravia, is included in one of the areas where a plebiscite is to be held Should this city, with its university erected after the War and named after President Masaryk, and its technical colleges and museum be transferred to Germany, it may well be asked how the republic is to continue The future of the German University of Prague (the only one provided for a minority in Europe) is also a matter for concern Will the Czechs feel justified in expending money upon it whilst their own establishments languish ? Whatever happens, it is highly probable that serious academic research such as the world has become accustomed to associate with Prague and its ancient university, will be impeded for a long time to come

The Physical Society

WHEN the Physical Society of London was founded in March 1874, a paper On the New Contact Theory of the Galvanic Cell was read by J A Fleming (now Sir Ambrose Fleming) Since then sixty four years have elapsed yet this veteran physicist and engineer is still taking part in scientific work It is therefore with particular interest that we see the announcement in the Society s programme that he is to give an address on January 13 next, on Physics and Physicists of the Eighteen Seventies Other noteworthy meetings included in the programme are the twenty third Guthrie Lecture by Prof A V Hill, on the transformation of energy and the mechanical work of muscles (Nov 11), a discussion on electro acoustics, to be opened by Dr C V Drysdale (Dec 9), discourse by Dr J D Cockcroft on the cyclotron and its applications (Jan 3), discourse by C S Wright on geophysical research in Polar regions (Jan 4), joint meeting with the Royal Astronomical Society for a discussion on the expanding universe, to be opened by Prof G F J Temple and Dr G C McVittie (Jan 27), the Thomas Young oration by Brigadier M N MacLeod on some recent developments in British surveying instruments (March 24), and joint meeting with the Chemical and Royal Meteorological Societies for a discussion on chemical and physical investigations of the upper atmosphere, to be opened by Prof F A Paneth (May 4) The president of the Society this year is Prof Allan Ferguson, and it is evident from the programme that he desires the meetings to be of wide interest and not confined to the communication of technical papers which are better presented by title for publication in the *Proceedings* than read

Roman Villa in Yorkshire

REMAINS of a Roman villa have been brought to light, contrary to anticipation at Well, a village of the Dales in the North Riding of Yorkshire Although the site was known to be Roman, it was thought to be too far north to be likely to provide evidence of occupation of any considerable interest As the result of a week of excavation, however, the walls of bath buildings, which had been connected with a villa, and the floor of the cold water plunge bath have been brought to light The floor has a tessellated pavement with plaster moulding, and the walls are plaster lined There is evidence that the walls had been twice rebuilt, once after a fire A piece of Huntcliffe' pottery indicates that occupation had been so recent as the last quarter of the fourth century Other pieces of pottery and a coin have been found Excavation is now being directed to a search for the hot bath room and the walls of the main buildings of the villa, which it is hoped to discover nearby In view of the geographical situation of the villa, this find is likely to prove of no little interest as an indication of the relation of civil settlement and military occupation, more especially at so late a date The excavation is being carried out under the supervision of Mr Gilliard Beer and Mr Kitson Clark of Leeds both members of the Roman Antiquities Committee of the Yorkshire Archæological Society It is stated in a report on the excavation, which appeared in *The Times* of September 28 that owing to lack of funds it will not be possible to continue the work of excavation beyond the middle of October It would, indeed be unfortunate if what may prove an important investigation in its bearing on a critical period should have to be abandoned before completion

Houses of Viking Age in Eire

PROVISION for archæological exploration and research continues to be made as part of the measures for the relief of unemployment put into operation by the Government of Eire In the systematic plan of archæological investigation which it has been possible to frame as a result of the resources, financial and other, made available in this manner, the exploration of the forts which form such an important class of Irish antiquities, naturally take a prominent place An account of the results obtained in an examination of one such site on Lough Gur, Co Limerick, of which the excavation was carried out under the supervision of Prof S P O Riordain in the present season, is given by a correspondent of *The Times* in the issue of October 3 These results are of special interest as the excavation of the fort brought to light evidence of the character of the house in Ireland in, it would appear from the associated finds the period of the Vikings about A D 800–1000 Both inside the fort and outside its walls were the remains of several houses built of stone One of them outside the southern rampart, was a long rectangular structure, built in such a way that the face of the wall of the fort formed a wall of the house The houses outside the wall to the north were provided with yards Although of different types, all were of stone They were paved, and in some of the rooms were hearths In one building the roof had been supported by timber posts, for which the holes were found A large number of objects for everyday use of iron, bronze, stone, and bone were found, which serve to date the site as of the Viking period A coin has been identified as an imitation, or copy, of a coin of Constantine, such as continued to be made in Britain long after the Roman period A hoard of Viking silver would appear to have belonged to a metal worker, and included silver bracelets which had been broken up preparatory to being melted down

Atmospheric Pollution

Readers of the daily Press might excusably conclude that physical fitness is solely a matter of physical exercise It appears to be taken for granted that everyone has free access to the essentials of wholesome food, water and air Yet the free access to good air does not in fact exist in our large towns and without it full advantage of facilities for physical culture cannot be taken For this reason it is of timely interest to inquire how efforts progress towards improving urban atmosphere The twenty third report of the Investigation of Atmospheric Pollution (H M Stationery Office 7s 6d) discloses statistical evidence of slight improvement, but cautiously expressed One large city at any rate—Leicester—has started an intensive survey of its own area and surroundings At twelve stations, systematic records will be taken of pollution by suspended matter sulphur impurities and of ultra violet light Although the collection of data may of itself effect nothing it may stimulate and provide a guide to ameliorative action Previous reports have directed attention to the considerable atmospheric pollution of central London In this one, a recommendation is reported by a committee formed on the initiative of the London County Council, to reduce the emission of grit which modern practice of intensive firing seems to promote This recommendation refers to the important contribution which could be made to the diminution of the grit and dust nuisance if they themselves [that is public authorities] made a practice in their municipal undertakings of using washed coal wherever possible and if they would press industrial undertakings in their respective areas to do so This is a timely recommendation for public authorities control a very large amount of fuel using plant and some do not by any means set a good example

Shale Oil Industry

The present position of the shale oil industry was clarified at an International Congress held in Glasgow in June last under the auspices of the Institution of Petroleum Technologists Dr E F Armstrong reports (*J Roy Soc Arts*, August 12 1938) that at the beginning of the Great War the yearly production of shale reached a maximum of 3¼ million tons to day only about half this quantity is produced This is partly due to the fact that the oil yield is directly proportional to the fossil algæ content of the shale, from which it is believed to originate this fossil algæ content is less in the lower and geologically older shale strata Thus the average yield to-day is 16–20 gallons per ton, whereas, in 1875, it was 30 gallons per ton Rapid development of natural petroleum has also influenced the shale industry Shale has to be mined and distilled before oil can be obtained and, therefore, without some form of protection, shale oil cannot compete with petroleum oil Nevertheless, in spite of obvious handicaps, the shale oil industry is being kept alive in Great Britain and other countries, and it may be that at some future date when natural resources of petroleum have been depleted it will become a major industry, particularly as it is capable of producing both Diesel oil and motor spirit

International Studies of Health

In May 1937 the Health Committee of the League of Nations decided to organize a sixth meeting of the directors of institutes and schools of hygiene in Europe These periodic meetings consider the studies carried out by the institutes as co ordinated by the Health Organisation and the future programme of activity At their meeting last November, the directors agreed that the institutes represented should undertake studies on health indexes, enteric fever, brucellosis the incidence of tuberculosis and methods of tuberculosis control and nutrition in rural areas The studies are to be co ordinated by the Health Committee and technical meetings of representatives of the institutes concerned have been organized by the Committee in preparation for the European Conference on Rural Life the Preparatory Commission of which has commenced its labours M A Wauters, the Belgian Minister of Health who was elected president of the Commission stressed the value of the scientific work it was undertaking independently of the international situation Particular questions which are being examined by the Commission with a view to inclusion in the agenda of the Conference are the problem of raising the standard of living the development of agricultural credits , the results of the inquiry on nutrition , the study of housing problems medical equipment in rural districts physical education and the combating of certain diseases which have particularly serious consequences in rural districts The Preparatory Commission includes a certain number of persons who have undertaken responsible work for their Governments in rural life

Cultural Pedigrees Some Recent Examples

Some interesting examples of culture lag and pedigrees of cultural elements are afforded in several of the articles which appear in *Antiquity* of September Of these the most considerable is Dr E Cecil Curwen s note of The Hebrides in which it is argued that If we had visited Lewis even fifty years ago, we should have been able to study the life and manners of a Celtic speaking race emerging from roughly the same state of culture as the Celtic people of the pre Roman Iron Age in Wessex Dr Curwen naturally devotes careful attention to the details of the still numerous but disappearing black house and the now disused beehive shielings a survival of the megalith builders in use fifty years ago Of the black houses he remarks that it is only since the recent introduction of tuberculosis that they have become unhygienic, and that in the seventeenth and eighteenth centuries centenarians were far more common in the island than they are now, even attaining the ages of 140 and more A contribution to the pedigree of the St George cult is made in an article, in translation, by Dr Gawril Kazarov, in which he links St George with the numerous pre Christian rider hero cult shrines and figures of Thrace The hero cult survives in Bulgaria in folklore, the siting of shrines, and the overwhelming importance of St George's day in the popular festal calendar. An inquiry on somewhat similar lines by Mr Stuart Piggott traces Hercules, "the simple good-hearted strong man", back to Akkad, c 2550 B C, and in post classical Europe down to Harlequin, a polished and sophisticated version of the god of the underworld The discerning will note that *Antiquity* shows no falling off in demonstrating practically that solid learning need not be dull

Protecting Marine Cables

ONE of the most prolific sources of damage to ocean cables is the heavy drags called otterboards which are attached to the nets of steam trawlers and dragged along the ocean bottom In the *Nickel Bulletin* of September it is estimated that the damage caused to cables by the steel runners of otterboards averages about £100 000 a year To get rid of this source of loss, the Western Union Telegraph Co has for some time, been experimenting with a submarine plough which will automatically make a furrow in the bottom of the ocean, feed the cable into it and cover it up The cable will then be buried at a depth sufficient to ensure that the otterboards cannot come into contact with it Encouraging results have been obtained from experiments made so far, but many difficulties have had to be faced A new series of experiments has now been started off the Irish coast The plough is towed by the cable ship *Lord Kelvin* In handling the equipment a very flexible towing line had to be provided able to withstand a load of 29 tons The ordinary equipment necessitates that the line must be neither too light nor too rigid It must be capable of being paid out gradually from the ship while ploughing under full load After careful investigation and a series of tests it was found that di lok', a special chain made of 3½ per cent nickel steel, was quite suitable In order to get continuously smooth operation a very minute tolerance on the size and shape of each individual link was imposed The requirements were about five times as severe as those imposed by the U S Navy in their specifications There are eleven Western Union trans Atlantic cables and eight of these pass through fishing areas off the Irish coast where most of the ploughing work will be carried out

Carnegie Institution of Washington

A VALUABLE addition to the administration building of the Carnegie Institution of Washington has for some time been under construction and will probably be completed in time for the usual Institution lectures in late October or early November The new structure has been designed primarily to facilitate development of the public relations programme of the Institution by improving conditions for handling its publications, and for more direct contacts with the public through lectures, conferences and exhibitions The principal room in the addition is an auditorium, designed to seat about five hundred which, under the name of Elihu Root Hall, is being dedicated to the memory of Mr Root Up to the present time the facilities for lecture programmes have been limited to a room seating comfortably about half that number, and it has been necessary in most cases to limit invitations to those who have something more than a general interest in the subjects presented With the accommodation now in preparation it will be possible to include a larger invitation list with freedom to invite men of science and laymen representing all fields of interest Committee and conference rooms have been designed for the special purpose of arranging for discussions with a limited group of special students of subjects under consideration, and thus promote inquiries and research into the particular field of natural knowledge in which they are engaged

THE exhibitions of the Institution held in recent years at the time of the annual meeting have served an important purpose in bringing together representatives of all the departments and in presentation of some of the most important results of their researches These contacts have had much value in development of co operative relations between research groups of the Institution The exhibitions have also served an important purpose in that they make possible the contact of the Trustees at the time of the annual meeting with all of the departments especially through giving opportunity to see results of some of the most interesting investigations In past years, the annual exhibition has been possible only by use of the regular offices of administration to the exclusion of much of the ordinary business at the time of the annual meeting The new building will include rooms which are much more commodious and better organized for exhibition purposes than those thus far available, and use of these quarters will permit the regular business of the administrative offices to be carried on during the period of the annual meeting The new exhibition rooms will also permit certain exhibits at the administration headquarters to be retained throughout the year if this seems desirable

The Institution of Professional Civil Servants

THE nineteenth annual report, for 1937, of the Council of the Institution of Professional Civil Servants refers to the spectacular increase in membership from 9,076 in 1935 to 13,896 at the end of 1937 Activities of the Institution during the year were directed largely to obtaining improvements in the salary scales of its members Despite the multiplicity of grades and salaries, considerable success has been achieved both by negotiation and by arbitration The common scale possessed by certain architectural surveying and civil engineering grades in the Civil Service enabled the Institution to secure improved salary scales by central discussion, and acceptance of the Institution's proposals for the simplification of grades and salaries of the professional, scientific and technical classes in the Civil Service which were submitted to the Tomlin Commission would greatly reduce the task of negotiation and lighten the work of the departmental establishment officers The Institution has also participated in the work of the National Whitley Council, and the report includes a full account of discussions on the increased cost of living. It has also taken part in the consideration of problems involved in the reorganization of the Post Office through its Post Office Committee, and the Post Office Engineering and Stores Departmental Whitley Council. Preliminary consideration is also being given to the adequacy of the Carpenter scheme in view of the magnitude and rapidity of developments in scientific establishments since the publication of the Carpenter Report in 1930.

The Strangeways Laboratory

In the report for 1937 of the Strangeways Research Laboratory, Cambridge, the trustees are able to announce that an anonymous donor has guaranteed an additional £500 a year to the income of the trust for five years. This subscription has enabled the trustees to accept the offer of the Rockefeller Foundation of the capital cost of an extension. The new buildings will provide additional accommodation for laboratory work, and will enable satisfactory arrangements to be made for the library and the workshops. During the year, the record number of twenty-five persons has worked in the Laboratory, and it is a testimony to its reputation that of these eleven should be visitors from other laboratories in Great Britain and abroad. The British Empire Cancer Campaign has equipped the Laboratory with a 200 kv. X-ray apparatus, and has purchased a 300 mgm. radium plaque, which had been on loan. This has enabled the work on the irradiation of tissues to be continued, and it is now being extended from the preliminary observations *in vitro*, to the more difficult problems encountered *in vivo*. Of the sixteen papers published from the Laboratory during the year, nine are concerned with embryological problems, three with the effects of radiation on living material, and the remainder with the metabolism of tumour tissue and the physiology of the embryonic heart.

Forest Products Research Board

The report of the Forest Products Research Board for the year 1937 forms an introduction to the report of the Director of Forest Products Research at Princes Risborough for the same year (London: H.M. Stationery Office, 1938. 2s. net). The Research Board briefly reviews the work of the year and the measures laid down to be observed in future in the preparation of reports on mechanical tests of timbers, the grading of structural timbers, and plywood and other materials built up from wood. An extensive investigation into the latter and allied materials is proposed, a study being made of 'composite wood', that is, of industrial materials made of laminated or disintegrated wood. An investigation is also to be carried out into the possibility of producing from home-grown timbers charcoal for use in the chemical and other industries, a prominent manufacturing firm having made an offer of a grant towards the cost of this work. The Director in his report acknowledges the important direct help which the physicist and chemist can give to the various branches of the timber-using industry.

Central Medical School, Fiji

The Central Medical School at Suva, Fiji, founded in 1929, of which an account was given by Sir James Barrett in Nature of September 11, 1937, p. 472, has recently issued its annual report for 1937. During the year there were 43 students in the school, 13 of whom were in their first year, 13 in their second, 14 in their third and 3 in their fourth. In addition to students from Fiji, the school was attended by students from Samoa, Tonga, Cook Islands, Gilbert and Ellice Islands, Solomon Islands, New Hebrides and Nauru. The approximate annual cost for each student was £74, which included board and lodging, tuition fees, maintenance expenses, clothing, servants' wages, and pocket money; so that the four years course of study amounted to about £300 per student. The average number of Fiji students who qualify each year is four and there is an average annual loss of two. In Fiji, there is one native medical practitioner for every 1,600 of the population, and if the seven Indian medical practitioners and the 86,000 Indian population are included there is one qualified man for 2,700 of population. Lists of the lecturers, prize winners and text books used at the school are included in the report.

Social Services and Venereal Disease

The Secretariat of the League of Nations has recently issued an account of the systems prevailing in different countries for the provision of social, as well as medical services in the treatment of venereal disease ("Social Services and Venereal Disease". Geneva: League of Nations; London: Allen and Unwin, 1938. 1s. 3d.). The necessity for cheap medical treatment for venereal disease is now widely recognized, in some countries is compulsory, in others including the United Kingdom, it is voluntary but is encouraged by the State. There is not the same wide recognition of the need for social help, and the number of countries where social service is combined with medical treatment at clinics and hospitals is still comparatively small. Where they exist these social services take different forms. An account is given in the booklet of the systems in use in the United Kingdom and France, and suggestions are given for future planning which should prove of value to social workers in all countries.

Yields of Fruit and Vegetables

Some figures issued by the Ministry of Agriculture on September 2 outline the condition of various horticultural crops in many centres of Great Britain. Whilst the main interest of this survey is doubtless economic, it should also be interpreted as indicating a potent need for research into the cropping of fruit trees. Apple yields of Bramley's Seedling, Cox's Orange Pippin and cider varieties have only amounted to between 10 and 40 per cent of their capabilities. They were somewhat higher in 1937, but even then the crop average was decidedly below 50 per cent. Runner beans, Brussels sprouts, cabbage, carrots, parsnips, peas and onions yield, in general, crops of 60–80 per cent, and were slightly better last year. The poor cropping of the apple for 1937 and 1938 revealed by these returns is not an isolated instance, for the crop of 1935 was also very low Damage by spring frosts and inadequate pollination are doubtless causes of low yield, but it should be possible for modern science to raise the apple's cropping potentialities above 50 per cent in most years

A Practical Form of Electrophoresis Apparatus

IT has long been known that proteins differ widely in their rates of migration in an electric field, and many attempts have been made to use this phenomenon for purposes of separation and identification by so called 'electrophoresis' The principle is particularly attractive since even highly unstable substances are unlikely to be damaged by the treatment One is therefore at first surprised at the scanty results yielded so far by so promising a method The reason is that until recently no apparatus had been designed which could claim to have overcome the many technical difficulties In the last few years however, there has been steady improvement in this respect, associated largely with the names of Dr Theorell of Stockholm and Prof Tiselius of Uppsala The latest form of Tiselius apparatus, which has now been placed on the market by Messrs F Hellige and Co, of Freiburg, enables the separation to be followed both optically and analytically, while the resolving power for small differences of mobility has been greatly increased A direct result of these improvements has been the detection and isolation of the three components of serum globulin (Tiselius, *Biochem J*, **31**, 1464, 1937) which has answered an old and much disputed question The apparatus is already in use in several other laboratories, and promises a host of further interesting results, for example, in the study of pathological sera, immune bodies and enzymes

Quekett Microscopical Club

THE Quekett Microscopical Club is holding its annual conversazione on October 11 at 7 30 p m at Burlington House, Piccadilly, London, in the rooms of the Royal Society Dr Arnold Renshaw of Manchester will lecture upon the microscope in the detection of crime It is not generally known that pieces of tissue (flesh, etc) can be cut in slices so thin as a twenty five thousandth of an inch A film made by Mr Pittock of the Department of Anatomy and Embryology, University College, Gower Street, will be projected following Dr Arnold Renshaw's lecture, showing all the stages in preparation and the actual cutting of these sections Eighty microscopes will be set up each showing different specimens In addition there will be several demonstrations Mr Edwards of the Haslemere Museum will give continuous projection during the evening of living pond life A group of members will show the method of collecting, cleaning, etc , of Diatomaceæ Methods of recording by means of drawing specimens and structures seen under the microscope will also be demonstrated Dr Gunther, of the Old Ashmolean, Oxford, will stage a demonstration of contributions by the late Mr E M Nelson to microscopy In addition to this Dr Gunther will give a demonstration of the original works of Hooke, showing proofs of the plates and the first editions of his book It is hoped that the Royal Society, which owns a Hooke microscope, will exhibit it. Demonstrations are also expected from the British Museum (Natural History), King's College, Queen Mary College, etc Cards of admission can be obtained from the Assistant Secretary Miss Arnold 58 Warwick Road, Ealing, W 5

Announcements

DR HAROLD J PLENDERLEITH has been appointed deputy keeper in charge of the research laboratory of the British Museum in succession to Dr Alexander Scott, who has been honorary director of the laboratory since its institution in 1919

THE following representatives to the Scientific Advisory Committee of the Trades Union have recently been appointed by the General Council Mr J Hallsworth (chairman of the General Council), Mr E Bevin, Mr J Brown, Mr C Dukes, Mr H H Elvin Mr G Gibson, Mr W Holmes, Mr W Lawther, Mr G W Thomson, and Sir Walter Citrine On advice furnished by the general officers of the British Association the scientific representatives on the committee will be nutrition and agriculture Sir Daniel Hall and Sir John Orr, physics, Prof Allan Ferguson and Prof P M S Blackett, chemistry, Prof F G Donnan and Prof A C G Egerton, physiology and psychology, Prof Winifred Cullis, population, Prof L Hogben, metallurgy, Prof J D Bernal, geology and geography, Prof P G H Boswell, engineering, Mr J S Wilson

THE Hydrobiology and Fisheries Laboratory Alexandria, a description of which appeared in NATURE of June 18, p 1107, has, by Royal decree, been named the Fouad I Institute of Hydrobiology and Fisheries

THE fiftieth anniversary of the foundation of the Pasteur Institute of Paris will be celebrated on October 26 in the presence of the President of the French Republic and the Minister of Health

THE American Academy of Arts and Sciences gives notice of the Francis Amory Septennial Prize for outstanding contributions to knowledge of diseases of the human sexual organs The first award, which will be made in 1940, will exceed 10,000 dollars There will be no formal nomination and no formal essays or treatises will be required Further information can be obtained from the Amory Fund Committee, American Academy of Arts and Sciences, 28 Newbury Street, Boston, Mass , U S A

A PRINTED supplement (Bulletin 1937, No 3, Supplement No 1, Washington, G P O , 1938 10 cents) to the index to Public Affairs Pamphlets has now been issued by the Office of Education, United States Department of the Interior It contains an annotated list of a further 552 pamphlets together with a report on the pamphlet display demonstration centres, and author, subject and title indexes

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return or to correspond with the writers of rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK S LETTERS APPEAR ON P 675

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Flow Phenomena in Liquid Helium II
